This work presents the results of uniaxial compression tests on freshwater polycrystalline ice. Grain size of the test material ranged from 1.5 to 5 mm, strain rate ranged from 171,000,000 to 17100/s and the temperature was -5 C. The grain size effect emerged clearly as the strain rate increased to 17100,009/s and persisted to the highest applied strain rates. On average, the stated increase in grain size brought about a decrease in peak stress of approximately 31 percent. The occurrence of the grain size effect coincided with the onset of visible cracking. The strength of the material increased to a maximum at a strain rate of 171,000/s, and then dropped somewhat as the strain rate increased further to 17100/s. Strain at peak stress generally tended to decrease with both increasing grain size and increasing strain rate. The results are discussed in terms of the deformation mechanisms which lead to the observed behavior.

MP 1908 TENSILE STRENGTH OF MULTI-YEAR PRES-SURE RIDGE SEA ICE SAMPLES

PRESSURE RIDGES, ICE STRENGTH, TENSILE PROPERTIES, SEA ICE, STRAINS, TESTS.

TROPERTIES, SEA LCE, STRAIRS, 1ES13. Thirty-sux constant strain-rate uniaxual tension tests were performed on vertically oriented multi-year pressure ridge samples from the Beaufort Sea. The tests were performed on a closed-loop electro-hydraulic testing machine at two strain rates (1/10,000 and 1/1,000/s) and two temperatures (-20 and -5 C). This paper summarizes the sample preparation and testing techniques used in the investigation and presents data on the tensile strength, initial tangent modulus, and failure strain of the ice.

COMPARISON OF SPOT SIMULATOR DATA WITH LANDSAT MSS IMAGERY FOR DELI-NEATING WATER MASSES IN DELAWARE BAY, BROADKILL RIVER, AND ADJACENT WETLANDS.

Ackleson, S.G., et al. Aug. 1985, 60(8), p.1123-1129,

WATER RESERVES, REMOTE SENSING, HYDRODYNAMICS, RADIOMETRY, LANDSAT, WATER FLOW, DELAWARE BAY.

DNODYNAMICS, RADIOMETRY, LANDSAT, WATER FLOW, DELAWARE BAY.

The radiometric and spatial qualities of SPOT simulator and Landsat-3 MSS data are compared as to their ability to distinguish different water masses within Delaware Bay and z ljacent weiland areas. The SPOT simulator data contain a greater range of gray level values for all water careas than do the Landsat MSS data. The greater spatial resolution of the SPOT simulator data provides information about small-scale hydrodynamics not available on the Landsat MSS data. Both types of data show a plume of spectrally unique water flowing from Roosevelt Inlet into Delaware Bay. The plume is most visible in SPOT simulator band it (300-590 nm) and Landsat MSS band 4 (500-600 nm). In both bands, the plume appears dark relative to the surrounding Delaware Bay water. Recent hydrographic surveys characterize the plume as an ebb itial feature with high concentrations of dissolved and particulate organic matter believed to originate from the adjacent Canary Creek Marsh and Great Marsh. SPOT simulator data are found to delineate water masses with a high degree of separation Radiometrically degraded SPOT data produce similar results Landsat J MSS data, although useful for delineating water masses, do not produce good separation because of sensor noise

SIMULATED SEA ICE USED FOR CORRELATING THE ELECTRICAL PROPERTIES OF THE ICE WITH ITS STRUCTURAL AND SALINITY CHARACTERISTICS.

The complex relative dielectric permittivity of saline ice The complex relative dielectric permittivity of saline is slabs removed from an artificially grown rec sheet has been measured at 4.75 GHz as a function of temperature. The frequency lies within the range used by other researchers who conducted radiometric tests concurrently on the same ice sheet. The slabs were placed between open waveguide radiators and defectine properties calculated from the forward scattering coefficient. The results show both real (k²) and imaginary (k²²) parts to vary almost in direct proportion to the brine volume. However, the values for k² show more variation, probably due to scattering.

LABORATORY STUDIES OF ACOUSTIC SCAT-TERING FROM THE UNDERSIDE OF SEA ICE. Jezek, K.C., et al. International Geoscience and Remote Sensing Symposium (IGARSS '85). Amherst, MA, Oct. 7-9, 1985. Digest, Vol. 1. New York, Insti-tute of Electrical and Electronics Engineers, Inc., 1985, p.87-91.

ICE ACOUSTICS, ICE BOTTOM SURFACE, SEA ICE, ATTENUATION, REMOTE SENSING, ACOUSTIC MEASUREMENT.

ACOUSTIC MEASUREMENT.

An analysis has shown that reflection coefficient for growing see is about .06

This coefficient increases dramatically as the see decays.

At frequencies above 100 kHz, exittering is dominated by the orienties at the base of the see. Fluctuations in normal incidence echoes are significant above 100 kHz.

Backscatter from the undertide of sea see does not change significantly as the size grows out of the melt (0 to 10 cm thick). Attenuation is found to be far greater than the attenuation reported by Langitchen who performed measurements horizontally and away from the dendritic sayer (same acoustic fromemers). (same acoustic frequencies)

SNOW DENSITY

Snow cover of both land and ocean (sea use) areas presents a challeng to remote sensing. On one hand, it acts as a mask over surfaces of interest and part of the remote sensing problem is then to deterrine whether the soom cover is transparent, opaque, or partially transparent resulting in an ariskinguous signature. On the other hand, the properties of the snow cover uself may be of interest, sine as depth, snow myter equivalent and coverage. Microwave remote securics of their capabilities to pentitate the surface, deter small wetness differences and operate in all weather condenses. (Foster, et al., 1945). To relate this potential in ordersant to understand how snow properties affect remote seame signatures. Microwave signatures of snow are a fanction

of diciectric constant as well as surface roughness and depth A primary objective therefore is to determine the relationship between the dielectric constant and environmental parameters, including physical properties of the snow cover and local meteorological variables

TY. Small-scale experiments were performed to determine sheet see forces on a conical structure. The experiments were conducted with a 45 deg, upward-breaking conical structure which had diameters of 15 m at the waterine and 0.33 m at the top. The surface of the structure was initially smooth, later it was initialized to investigate the effect of surface friction on the ice load. The thickness and the fleaural strength of ice sheets were varied, and the tests were conducted at three fixed velocities. The measured tests were conducted at three fixed velocities. The measured forces for tests conducted for a low coefficient of friction (0.1), whereas some velocity effect on the horizontal ice forces is found for tests conducted with the rough surface forces are higher at lewer vewcrities. The surface having a coefficient of friction equal to 0.5. The horizontal ice forces are higher at lewer vewcrities. The sure of the broken ice preces, determined from a power spectrum analysis of the horizontal ice force records, was found to be about one-third of the characteristic length.

40-825 SNOW CRYSTAL STRUCTURE, METAMOR-PHISM (SNOW), SNOW WATER CONTENT, FREEZE THAW CYCLES, CLASSIFIC. TO ICE CRYSTAL GROWTH, SNOW MELTING, SNOW COVER, GRAIN SIZE.

SNOW COVER, GRAIN SIZE.

It is necessary to assign terms to snow crystals so that we can refer to them at any time. TCSI (1954) suggested five classes of snow crystals but many in .c. tant types of crystals were not included. Sommerfel. '969) and then Sommerfeld and Lachapelle (1970) suggestal as classification based on processes because, if the processes could be correctly identified, information would be provided about both crystal shares and metamorphic processes. Unfortunately, many identified, information would be provided about both crystal shapes and metamorphic processes. Unfortunately, many of the names used—equitemperature, temperature gradient, and melt-freeze—can misrepresent the processes responsible for generating those shapes. Other terms are suggested here in hopes of correctly describing snow crystals. Only the major categories are dealt with here; a more detailed classification will be published later.

The method and equipment used to coincidentally determine the hydraulic conductivity versus soil moisture tension and

soil moisture tension versus moisture content relationships are described. Over 30 soils have been tested, including gravels, sands, silts and clays. Most of the work has been conducted at soil moisture tensions less than 100 kPa (1 bar), but a few moisture retention curves extend to about 12 bars of soil maintage quoties. 12 bars of soil moisture suction Results for one soil from each type are described and discussed in detail. Grain trom each type are described and discussed in detail. Grain size distributions and the two hydraulic relationships are shown for each of the four soils. An equation suggested by Gardner is used to approximate both relationships. Coefficients for Gardner's equations for several different soils have been obtained and are tabulated.

MODEL FOR DIELECTRIC CONSTANTS OF

FROZEN SOILS.
Oliphant, J.L., Freezing and thawing of soil-water systems. Edited by D.M. Anderson and P.J. Williams, tems. Edited by D.M. Anderson and P.J. Williams, New York, NY, American Society of Civil Engineers, 1985, p.46-57, 17 refs. 40-617

FROZEN GROUND PHYSICS, SOIL COMPOSITION, GROUND THAWING, UNFROZEN WATER CONTENT, DIELECTRIC PROPERTIES, TEMPERATURE EFFECTS, NUCLEAR MAGNETIC RESONANCE.

The dielectric constant of frozen soils is made up of contribu-tions from each phase—mineral, ice, air and liquid water —in the soil. Solinite, Morin clay and Palouse sit-loam, were measured under both thawed and frozen conditions at various soils, a kaominet, which they and readuse shrotain, were measured under both thawed and frozen conditions at various temperatures and various water contents using time domain reflectometry (TDR). Nuclear magnetic resonance (NMR) was used to measure the unfrozen water contents of these soils at subfreezing temperatures. The NMR data were used to calculate the volume fractions of the ice and liquid water phases in the TDR experiments. It was found that a mixing model for the apparent dielectric constant of the soil samples assuming spherical air, ice and minderal inclusions in a water matrix was able to closely fit the TDR data. To obtain the best fit it was necessary to use an average dielectric constant for water somewhat less than that for bulk water. The mixing model can be used for the interpretation of TDR data obtained in the field. This allows for the measurement of unfrozen water contents using TDR at temperatures just below 0 C, where the liquid water phase makes up a significant portion of the TDR signal.

CREEP STRENGTH, STRAIN RAIE, TEMPERA-TURE AND UNFROZEN WATER RELATION-SHIP IN FROZEN SOIL

Fish, A.M., International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Proceedings, Vol.2, [Rotterdam, A.A. Balkema, 1985], p.29-36, 32 refs.

FROZEN GROUND STRENGTH, SOIL CREEP, STRAINS, FROZEN GROUND TEMPERATURE, UNFROZEN WATER CONTENT, FROZEN GROUND PHYSICS, COMPRESSIVE PROPERTIES, TEMPERATURE EFFECTS, ANALYSIS (MATHEMATICS)

(MATHEMATICS)
A relationship was develope, between maximum (peak) strength, strain rate, strain, and temperature using data on unitaxial compression of remolded frozen Fairbanks silt obtained in the temperature range from -0.5 to -10. C at constant strain rates (CuR) that varied between 1/100 and 1/1,000,000/s. It is shown that three principal parameters of frozen oul define the "agnitude of strength at a given strain rate, the instantaneous strength, the activation energy, and the strain hardenne parameters are the strain hardenne parameters. and the strain hardening parameter all relate to each other. Their absolute values depend upon temperature and are linked

with the simplest physical characteristics of soil and especially the ice and unfrozen water contents. The activation energy of frozen soil is presented as a sum of two components: activation energy of the soil skeleton and activation energy of the unfrozen water. The activation energy of frozen soil varied due to the changes of unfrozen water content between 16 6 and 13.2 kcal/mole.

PREDICTION OF UNFROZEN WATER CON-TENTS IN FROZEN SOILS BY A TWO-POINT OR ONE-POINT METHOD.

Xu, X., et al, International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Pro-ceedings, Vol.2, ¡Rotterdam, A.A. Balkema, 1985], p.83-87, 5 refs. Oliphant, J.L., Tice, A.R.

FROZEN GROUND, UNFROZEN WATER CON-TENT, DENSITY (MASS/VOLUME), TEMPERA-TURE EFFECTS.

The unfrozen water content in frozen soils, with different initial water content, dry density and molality, was determined by the nuclear magnetic resonance technique. Results show that the unfrozen water content in frozen morin clay changes with the initial water content and the dry density only within a range of three percent of the dry soil weight, and increases with the increase in the molality linearly because of the linear freezing point depression. The curves of the unfrozen water content vs temperature are quite parallel with the change in the initial water content and rots'e a little bit counterclockwise with the increase in the dry density. On the basis of the data mentioned above, a two-point method by the measurements of two freezing points at two different initial water contents, and a one-point method by the measurement of the unfrozen water content at The unfrozen water content in frozen soils, with different at two different initial water contents, and a one-point method by the measurement of 'he unfrozen water content at - 1 C if the initial water content and its freezing point are given, is presented.

Errors of predicting the unfrozen water content are 1-3% on the average for the two-point method and 1% or so for the one-point method.

URES.
The magnitude and variation of forces and shear stresses, caused by soil frost heaving, for a pipe pile and an H pile were determined as a function of depth along the upper 3 m of the piles for two consecutive winters. The maximum frost heaving forces on the H pile during each winter were 943 kN and 899 kN The maximum frost heaving force on the pipe pile was 703 kN Maximum local shear stresses for the H pile were 1 MPa and 903 kPa for the two winters. The maximum local shear stress for the tipe pile was 896 kPa Maximum average shear stresses over the two winters were 324 kPa and 427 kPa for the pipe pile and 324 kPa for the pipe pile. Maximum heaving forces and shear stresses occurred during periods of maximum cold and soil surface heave magnitude. These were related to the depth of frost for most of the winter the soil was frozen completely to the permafrost table.

SHEAR STRENGTH ANISOTROPY IN FROZEN SALINE AND FRESHWATER SOILS.

Chamberlain, E.J., International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Proceedings, Vol.2, [Rotterdam, A.A. Balkema, 1985], p.189-194, 2 refs. 40-687

FROZEN GROUND STRENGTH, SHEAR STRENGTH, ANISOTROPY, SALINITY, CLAY SOILS, SANDS, TESTS.

The shear strength anisotropy of frozen freshwater and seawater clay and sand soils was investigated using the direct shear technique. Samples were sheared at angles of 0, 30, 60 and 90 degrees between the shear and freezing planes. and yo degrees between the shear and freezing planes. Because of variations in sample density, there was considerable scatter in the data. This scatter and the relationship of the maximum shear strength to the angle between the shear and freezing planes were accounted for by conducting multiple linear regression analysis on empirical equations relating the test variables to the shear strength. MP 1932 SOIL-WATER POTENTIAL AND UNFROZEN WATER CONTENT AND TEMPERATURE.

FROZEN GROUND TEMPERATURE. CLEAR MAGNETIC RESONANCE, UNFROZEN WATER CONTENT, SOIL WATER, SOIL STRUC-TURE, WATER CONTENT, FREEZING POINTS, SOIL CHEMISTRY, SOIL TEMPERATURE, DEN-SITY (MASS/VOLUME).

SITY (MASS/VOLUME).
Soil-water potential was determined by the extraction method and four factors affecting the soil-water potential, including water content, soil type, dry density and temperature, were investigated. The unfrozen water content of frozen soils was determined by the pulsed nuclear magnetic resonance technique and three factors affecting the unfrozen water content, including initial water content, dry density and salt concentration, were investigated. Results have shown that the soil-water potential in the unsaturated, unfrozen soils decreases both with the decrease in the water content and with the increase in the dispersion of the soil and increases with the increases in the dry density and temperature. The unfrozen water content and the dry density and temperature with the increase in the salt concentration.

40.830

40-830 UNFROZEN WATER CONTENT, FROZEN GROUND PHYSICS, SALINE SOILS, ELECTRI-CAL RESISTIVITY, SOIL CHEMISTRY.

CAL RESISTIVITY, SOIL CHEMISTRY.

Phase composition curves are presented for a typical saline sailt from Lanzhou and compared to some silts from Alaska. The unfrozen water content of the Chinese silt is much higher than the Alaskan silts. This higher amount is due to the large amount of soluble salts present in the silts from China which are not present in the silts from miterior Alaska. When the salts are removed, the unfrozen water contents are then similar for the Chinese and Alaskan silts. We have introduced a technique for correcting the unfrozen water content of partially frozen soils due to high salt concentrations. This correction is possible by calculating the modality of the unfrozen water at each temperature from a measurement of the electrical conductivity of the extract of a saturated paste.

PRESSURE RIDGES, ICE STRUCTURE, ICE PHYSICS, SEA ICE, SALINITY, GROUNDED ICE, ICE CRYSTAL STRUCTURE, ICE FLOES. GRÉENLAND SEA.

Field investigations of pressure ridge sails have shown that ridge height is limited by the thickness of the ice that deformed sail height and width can be conveniently expressed as functions of the thickness of the ice blocks contained in the ridge Surface dimensions of the blocks. expressed as functions of the thickness of the ice blocks contained in the ridge. Surface dimensions of the blocks are also related to ice thickness. Ridge height may be determined by the ability of the parent sheet to support the loading imposed by the ridge or by the type of failure occurring. Some insight into the structure of ridge keels may result from detailed study of the sails. The physical properties of sea ice in the Fram Strait region of the Greenland Sea were examined as part of the MIZEX field program in 1984. The properties measured at each sampling site included salinity, temperature, thickness, crystal structure and snow depth. The measured salinities agreed well with those measured elsewhere in the Arctic during summer Crystal texture analysis indicated that about 75° of the ice consisted of columnar type crystal structure. The remaining 25% consisted of granular ice.

MECHANICAL PROPERTIES OF MULTI-YEAR PRESSURE RIDGE SAMPLES.

Richter-Menge, J.A., Arctic Oceanography Conference and Workstop, Hatricsburg, MS, June 11-14, 1985. Proceedings, U.S. Department of the Navy, 1985, p.244-251, 19 refs.

PRESSURE RIDGES, ICE MECHANICS, COM-PRESSIVE PROPERTIES, TENSILE PROPER-TIES, ICE DENSITY, MECHANICAL TESTS, SALINITY

Over 500 laboratory tests have recently been completed on ice samples collected from multi-year pressure ridges in the Alaskan Beaufort Sea. Tests were performed in uniaxial constant-strain-rate compression and tension and in confined compression. The tests were conducted at two temperatures, -5 and -20 C, and four strain rates ranging from 1/100 to 1/100,000/s. This discussions ammarizes the sample preparation and testing techniques used in the investigation and presents data on the compressive, tensile and confined compressive strength of multi-year ridge samples. This information is necessary for designing arctic structures and vessels that must withstand the impact of a multi-year pressive ridge. Over 500 laboratory tests have recently been completed

ICE NAVIGATION.

A biaxial ice stress sensor has been developed to measure the magnitude and direction of the principal stresses in an ice sheet. Controlled laboratory tests indicate that the sensor has a resolution of 20 kPa and an accuracy of better than 10% under a variety of loading conditions. The sensor has been successfully used to measure thermal ice pressures in lakes and ice loads on a caisson-retuined island in the Beaufort Sea.

ANALYSIS, STRATIGRAPHY, OCEAN CUR-RENTS

A simulation model for sea ice-induced gouges on the shelves of the polar seas is developed by assuming that the annual occurrence of new gouges is given by a Poisson distribution, the locations of the gouges are random, and the distribution of gouge depths is specified by an exponential distribution Once a gouge is formed it is infilled by assuming a sediment input based on stratigraphic considerations and by calculating bed-load transport using methods from sediment transport theory. If currents are sufficient to transport sediment, rapid infilling of gouges occurs. In that these threshold currents are small for typical grain sizes, this suggests that the gouging record commonly represents only a few tens of years

ICE CRYSTAL GROWTH, ICE CRYSTAL STRUC-TURE, SNOW CRYSTAL STRUCTURE, TEMPERATURE EFFECTS, PLATES, SURFACE ROUGHNESS. EXPERIMENTATION

ROUGHNESS. EXPERIMENTATION
Individual crystals are grown under controlled conditions at temperatures between -0.6 and -20.C at rates as low as 1.0,000,090. The transition between the kinetic growth form and the equilibrium form is clearly distinguished at temperatures between -2 and -10.C where the equilibrium form is a well rounded plate with an aspect ratio of about 2.5. At temperatures below -11.C the equilibrium form is a well rounded plate with an aspect ratio. This transition coincides with the rapid increase in surface roughening on the prism faces at temperatures above -10.C. The equilibrium form is a fully rounded particle just below 0.C aithough we had expected the fully rounded particle to prevail down to at least -5.C. Furthermore, there are unresolved differences between these experimental results and observations of crystals from the scasonal snow cover

where particles are fully rounded at slow growth rates and low temperatures.

ICE JAM FLOOD PREVENTION MEASURES: LAMOILLE RIVER AT HARDWICK, VER-

MONT, USA.
Calkins, D.J., International Conference on the Hydraulics of Floods and Flood control, 2nd, Cambridge, England, Sep 24-26, 1985 Proceedings, Cranfield, Bedford, England, BHRA, The Fluid Engineering Centre, 1985, p.149-168, 4 refs.

ICE CONTROL, ICE JAMS, RIVER ICE, FLOODS, WATER LEVEL, TOPOGRAPHIC EFFECTS, COUNTERMEASURES.

COUNTERMEASURES.
Prevention of ice-induced flooding is very difficult, but the impact can be minimized if the winter ice regime can be altered. The Lamoille River at Hardwick, Vermont, is a steep, shallow stream during non-ice periods. Under ice jam conditions stage increases of 1-2 m above the elevation of the floodplain have been implemented to minimize the ice jam flood levels, their performance was evaluated for the winter of 1983-84.

Phetteplace, G, Intersociety Energy Conversion Engineering Conference, 19th, San Francisco, CA, Aug. 19-24, 1984 Proceedings Vol 3, American Nuclear Society, 1984, p.1748-1752, 4 refs. 40-1688

COST ANALYSIS, HEAT TRANSMISSION, PIPE-LINES, LOADS (FORCES), DESIGN, ANALYSIS (MATHEMATICS), HEATING, COOLING, HEAT

Piping systems represent the major portion of the total cost of most district heating applications and constitute a barrier to their widespread implementation

This paper presents to their widespread implementation a methodology for least-cost design of these systems under realistic conditions of varying load. Cost-effective design of piping for district he ling and cooling applications requires careful consideration of the various components of the owning and operating costs. These costs are included in the formulation of an optimization problem to determine the minimum cost design on a yearly cycle basis.

MP 1943 NITROGEN REMOVAL IN WASTEWATER STA-BILIZATION PONDS.

Reed, S.C., (1983), 13p. + figs., Presented at 56th Annual Conference of the Water Pollution Control Federation, Atlanta, Georgia, Oct 2-7, 1983 Un-published manuscript 14 refs 40-1089

WASTE TREATMENT, WATER TREATMENT, WATER POLLUTION, PONDS, COUNTER-MEASURES, DESIGN CRITERIA, LAND REC-LAMATION, CHEMICAL ANALYSIS.

LAMATION, CHEMICAL ANALYSIS.

A rational procedure for estimating nitrogen removal in facultative wastewater stabilization ponds has been developed and validated. The procedure, based on first order plug flow kineties is dependent on pH, temperature and residence time. The model was developed from extensive data obtained at four facultative ponds in various parts of the US and was validated with independent data from five pond systems in the US and Canada. The procedure should be useful whenever system design enteria require nitrogen removal or ntiffication. It should be particularly helpful for the pond component of land treatment systems when nitrogen is the limiting design parameter.

A methodology for design of heat transmission lines is presented. It is based on finding the pipe diameter which yields the lowest total cost. Cost factors considered are cost of energy lost in the form of heat, cost of energy to produce pumping work, and cost of capital to construct the system. The methodology has been developed into a computer code which allows for rapid analysis of alternatives. Results are presented, based on certain assumptions, for various parameters of interest.

THEORIES.

THEORIES.

Buoyancy-driven flows of air in snow are modeled including the effects of phase change and inclination. Phase change between water vapor and uce is important because of latent heat terms in the energy equation. Upper boundaries of the snow are taken as either permeable or impermeable, with temperature or heat flux specified at the lower boundary. When the ratio of thermal to mass diffusivity is greater than 1, phase change intensifies convection. When this ratio is less than 1, phase change admps convection. The effects of permeable top and uniform heat flux bottom boundary conditions on heat transfer are quantified and described as linear functions of Ra/Ra(cr), where Rs is the Rayleigh number and cr refers to the critical value for the onset of Benard convection. The slope of each function depends only on the thermal boundary condition at the lower boundary for any nonzero Rayleigh number. Velocity profiles for flows in inclined layers with permeable tops are derived, and it is found that velocity is proportional to Ra sin phi, where phi is the angle of inclination from the horizontal. The numerical results for different boundary conditions compare reasonably well with experimental results from the hierature.

SNOWFLAKES, LIGHT SCATTERING, SNOW CRYSTAL STRUCTURE, PARTICLES, ICE NEEDLES, ANALYSIS (MATHEMATICS).

DLES, ANALYSIS (MATHEMATICS).

Measured extinction of light by particles, especially those larger than the wavelength of the light illuminating them, must be corrected for forward-scattered light collected by the detector. Near-forward scattering by arbitrary nonsiberical particles is, according to Fraunhofer diffraction theory, more sharply peaked than that by spheres of equal projected area. The difference between scattering by a nonsphenical particle and that by an equal-area sphere is greater the more diffusely the particle's projected area is distributed about its centroid. Snowlakes are an example of large atmospheric particles that are often highly nonspherical Calculations of the forward-scattering correction to extinction by ice needles have been made under the assumption that they can be approximated as randomly oriented prolate spheroids (aspect ratio 10 1) The correction factor can be as much as 20% less than that for equal-area spheres depending on the detector's acceptance 2 gle and the wavelength. Randomly oriented oblate-spheroids scatter more nearly like equal-area spheres. area spheres.

MP 1959 PEBBLE FABRIC IN AN ICE-RAFTED DIAMIC-

ICE RAFTING, GLACIAL DEPOSITS, SEDIMENTATION, MORAINES, STRATIGRAPILY, FOSSILS, ORIGIN, GLACIER FLOW.
Pebble fabric studies on ice-rafted diamictors have been imited to general observations, with authors noting preferences toward vertical, random, or horizontal ericinations. To clarify such observations, pebble fabric data were collected from a fossiliferous diamiction of late Pleistocene age located on Whidely Island, Washington. The ice-raftled origin of this unit is supported by several independent characteristics including in situ macrofauna and microfauna, conformity with subaquieous lithofacies containing dropstones, lower bulk densities and higher void ratios than associated tills, soft sedimer, deformation structures suggestive of iceberg dumping, textural gradations, and facies relationships. Analysis using the eigenvalue method indicates that ice-rafted fabrics are nearly random with little consistency of vector orientations between sites and without any relationship to the probable direction of glacial flow. The weak fabric is mainly the product of settling through the sater column and impact with, or penetration of, the bed. Samples that possess a weak preferred long axis orientation with a low angle of dip, including those from laminated muds, can best be explained by the intermittent effects of bottom currents, a resistant substrate at the time of deposition and post depositional flowage. Comparisons of pebble fabrics from basal tills, recent sediment flow deposits and basal, debrished in the of explaining the rafter deformation and post of existent flow diamictons lee-rafted diamictons appear, however, to contain a greater

number of elongate stones, with long axis plunge angles exceeding 45 deg, than other glacigenic diamictons

MP 1960 AUDIBILITY WITHIN AND OUTSIDE DEPOS-ITED SNOW.

Johnson, J.B., 1985, 31(108), p 136-142, 12 refs., In English with French and German summaries.

40-1320 SNOW COVER EFFECT, SNOW ACOUSTICS, SOUND TRANSMISSION, NOISE (SOUND).

Factors which control the audibility within and outside deposited show are described and applied to explain the preferential detection of sound by persons buried under avalanche debris as compared to persons on the overlying snow surface. Strong attenuation of acoustic waves in snow and the small acoustic impedance differences between snow and air are acoustic impedance differences between snow and air are responsible for the strong absorption and transmission-loss characteristics that are observed for snow. The absorption and transmission-loss characteristics are independent of the direction of propagation of acoustic signals through the snow. The preferential detection of sound by a person buried under snow can be explained by the relatively higher level of background acoustic noise that exists for persons above the snow can be called the control of the co sanw surface as compared to an avalanche burial victim. This noise masks sound transmitted to persons on the snow surface, causing a reduction of hearing sensitivity as compared to the burial victim. Additionally, the listening concentration of a buried individual is generally greater than for persons working on the snow surface, increasing their subjective awareness of sound. (Auth)

SOIL WATER, WATER FLOW, POROUS MATERIALS, CHANNELS (WATERWAYS), HY-DRAULICS, VISCOUS FLOW, LAMINAR FLOW, DIFFUSION.

DIFFUSION.

By comparing experimental measurements of the hydraulic conductivity and the effective self-diffusivity of water in porous media, a channeling parameter, c, is defined. This parameter measures the degree of division of flow paths in the media, but does not depend on the tortuosity of the paths or surface effects on the viscosity of the water. Values of c are obtained for Na-saturated montmortillomites containing from 0.82 to 7.7 g of water per g of clay and for Fairbanks silt containing from 0.135 to 0.23 g of water per g of silt. Values for the montmortillomites remain relatively close to the theoretically predicted value of 1/3 at all water contents, indicating maximally divided flow paths Values for the silt vary from 100 to over 2000, indicating highly channeled flow

BRITTLENESS OF REINFORCED CONCRETE STRUCTURES UNDER ARCTIC CONDITIONS. Kivekas, L., et al, 1985, No.369, 28 + 14p, In Finnish with English summary.

Korhonen, C.

WINTER CONCRETING, CONCIDENCES, LOADS (FORCES), RFIN (CED CONCRETES, CONCRETE STRUCKES), FRACTURING, IMPACA STRENGTH, TEMPERATURE EFFECTS

TEMPERATURE EFFECTS
When plain reinforcing bars are tested under impact load according to the steel standards their failure becomes brittle already at the arctic temperature region. However, when reinforced concrete structures are loaded with an impact load, the reinforcing bars are subjected to loading conditions very different from the test with the plain rebars, and this has a significant effect on the transition temperature.

ION AND MOISTURE MIGRATION AND FROST HEAVE IN FREEZING MORIN CLAY.
Qiu, G., et al, Mar. 1986, 8(1), p.1014, 9 refs., In Chinese with English summary.
Chamberlain, E.J., Iskandar, I.K.

FROST HEAVE, SOIL WATER MIGRATION, IONS, CLAY SOILS, SOIL CHEMISTRY, WATER CONTENT, FREEZING RATE, TESTS.

CONTENT, PREBZING RATE, 1ESTS.

Staten specimens made of Morin Clay with a saturation percentage of 86% were subjected to freezing tests in open system fed by distilled water, NaCl solution, CaCl(2) solution and Na(2)SO(4) solution respectively. Before freezing test, specimens were homogeneous in water content but heterogenespecimens were nomogeneous in water content out neterogene-ous in chemical composition with a vertical concentration gradient. After freezing test, both water content and the dominant-anion content in frozen part of the soil samples increase, this means that not only moisture but also ions were migrating toward the freezing zone during tests.

TENSILE STRENGTH OF FROZEN SILT.

40-463

40-40-35 FROZEN GROUND STRENGTH, TENSILE PROPERTIES, STRAIN TESTS, SEDIMENTS, SOIL COMPACTION, DENSITY (MASS/-VOLUME), TEMPERATURE EFFECTS.

VOLUME), TEMPERATURE EFFECTS.

Constant strain-rate tension tests were conducted on remolded saturated frozen Fairbanks silt at various temperatures, strain rates and densities. It is found that the critical strain rate of the ductile-brittle transition does not depend upon temperature, but varies with density It has a value of 0.01/s for the silt with medium density and 0.005/s for low density. The peak tensile strength considerably decreases with decreases with increasing strain rate for brittle fracture. The failure strain remains almost the same for temperatures lower than about -2C, but it varies with density and strain rate. The initial tangent modulus is found not to depend upon strain rate, but increases with decreasing temperature and density.

ICE BLOCK STABILITY.
Daly, S.F., Water for resource development, Proceedings of the ASCE Hydraulics Division Specialty Conference, edited by D.L. Schreiber, New York, American Society of Civil Engineers, 1984, p.544-548, 5 refs. 40-1548

40-1548
RIVER ICE, ICE FLOES, ICE PRESSURE.
In this paper a simple formulation of the forces acting on an ice block in contact with an intact ice cover is presented. Underturning of the ice block is the assumed mechanism by which the block is swept under the ice cover. The data can be divided into two separate cases, a shallow water case and a deep water case. The conditions of instability for each case are determined empirically. The resultant prediction of the velocity at which the block is swept under the cover reproduces the data very well over the entire range of nondimensional ice block thicknesses The "nospill" condition used in earlier formulations is not required.

TRUMENTS, SETTLEMENT (STRUCTURAL).

Theoretical and experiment studies of time-dependent deformation and failure of columnar-grained ice are presented Laboratory uniaxial compression tests at constant and steadily increasing stresses were accompanied by simultaneous recording of acoustic emissions. Strength criteria and constitutive equations were established, describing grain disintegration, microcrack initiation and acoustic emission dynamics during creep, and their relationship to the rheological properties of ice. The rheological properties of ice were studied under laboratory and field conditions using a pressuremeter, leading to the development of an in situ method for determining the mechanical properties of ice taking into account the the mechanical properties of ice taking into account the time factor. The results of the studies were applied in analyses of settlements of foundations on high-ice-content soils and ground ice Based on the comparison of experimen-tal data with calculated settlements, it is shown that the characteristics of ice used in the analysis can be determined either from laboratory tests or in situ, by means of a pressureme-

VIBRATION ANALYSIS OF THE YAMA-CHICHE LIGHTPIER.

Haynes, F.D., International Modal Analysis Conference, 4th, Los Angeles, CA, Feb. 3-6, 1986, Proceedings, Vol.1, Schenectady, N.Y., Union College, 1986, p 238-241, 11 refs 40-1881 DIERS, VIBRATION,

PIERS. VIBRATION, ICE LOADS, SHEAR STRENGTH, MATHEMATICAL MODELS, COM-PUTER APPLICATIONS.

To determine its dynamic characteristics, the Yamachiche lightp.cr located in Lac St Pierre, Quebec, was instrumented with geophones, accelerometers, and an inclinometer Fifteen breakable bolts with failure strengths from 45,000 to 450,000 N were used to apply a step unloading force on the pier. The damping and suffness were obtained from the data in the time domain. The natural frequencies The natural frequencies and mode shapes were obtained from the data tran

into the frequency domain. A modal analysis computer program was used to verify the natural frequencies and mode shapes. A mathematical model was developed that includes translation, rotation, and shear beam deformation

MP 1990 SOIL FREEZING RESPONSE: INFLUENCE OF TEST CONDITIONS.

McCabe, E.Y., et al, June 1985, 8(2), p.49-58, 22 refs. Kettle, R.L.

SOIL FREEZING, FROST HEAVE, SOIL COM-PACTION, FROST RESISTANCE, SOIL PRES-SURE, TEMPERATURE GRADIENTS, TESTS.

SURE, TEMPERATURE GRADIENTS, TESTS. The response of soils to freezing has been assessed in terms of frost heave, and the heaving pressure developed when the specimen is restrained. As both techniques have been suggested for assessing frost susceptibility, it was considered essential to determine the influence of the test conditions on the soil response. This investigation was concerned with specimen preparation, specimen size, and freezing procedure. The test material consisted of an artificially produced matrix, into which controlled amounts of coarse aggregate could be blended. This reduced the likelihood of variation in the results because of random changes in the test materials. The results clearly demonstrated the sensitivity of both heave and heaving pressure to the test conditions. When modified or new test methods are being formulated, it is essential to consider the influence of such factors, particularly when making comparisons between different testing techniques Such modifications may also require changes in the particular criteria used to assess frost susceptibility

ELECTROMAGNETIC PROPERTIES, COVER EFFECT, WAVE PROPAGATION, DIE-LECTRIC PROPERTIES, ICE SHEETS, PRO-FILES, VELOCITY, REFLECTION, REFRAC-TION.

TION.

The propagation of electromagnetic pulses in naturally occurring dielectric surface layers has been examined. Pulse duration used in field experiments reported here has been on the order of nanoseconds with pulse bandwidths in the high VHF to low UHF band. The layers were sheets of fresh water ice and grante at thicknesses ranging between 4 and 4 m. Both transverse electric (TE) and transverse magnetic (TM) modes were attempted but only the TE propagation could be interpreted. Analog recordings of wide-angle reflection and refraction (WARR) profiles were taken and recorded in a continuous graphic display. The displays allowed easy identification of phase fronts thereby facilitating study of the dispersion of the pulses. The phase and group velocities of the wave-group packets agree well with the velocities predicted from dispersion curves derived from the modal waveguide equation. In one case the Airy phase of wave-packet propagation occurred. The best measure of the dielectric constant of the layer was the frequency of the air wave. the frequency of the air wave

ICE DEFORMATION.
Shaped charges fired from air into ice give holes of typical form for cohesive solids. There are only a few reported results from test shots in ice, but supplementary data can be obtained by adjusting the results from tests in ice-bonded soil in accordance with target density. Present indications are that charges with narrow angle cones (appr. 45 deg) can penetrate about 16 cone diameters, giving a hole diameter near mid-depth of about 1/3 of the cone diameter. Charges with wide-angle cones (60-90 deg) might penetrate about 12 cone diameters, giving a hole diameter near mid-depth of about 2/3 cone diameters. Optimum standoff in air seems to be around 4 cone diameters. So far, we have no data for shaped charges fired into ice under water.

AIRPORTS, PAVEMENTS, FREEZE THAW CY-CLES, CRACKING (FRACTURING), DAMAGE, CLIMATIC FACTORS, DESIGN.

CLIMATIC FACTORS, DESIGN.
In early fall 1984, USACRREL conducted a study of airport pavements in cold regions of the United States. The most common pavement problems were associated with nontraffic related phenomena and include (1) pre-existing cracks reflecting through asphalt concrete overlays (in two years or less), (2) thermal cracking, and (3) longitudinal cracking (at a construction joint). Most of the airports experienced (1) water pumping up through cracks and joints in the pavements during spring thaw, or (2) additional roughness due to differential frost heave in the winter, or both problems Many airport managers reported that debris was generated at cracks during the winter and spring. Several airports experienced problems with lighting in the winter and spring. Many pavement problems can be traced to the evolutionary history of general aviation airports and the lack of consideration for site drainage.

LESSONS LEARNED FROM EXAMINATION OF MEMBRANE ROOFS IN ALASKA.
Tobiasson, W., et al. International Conference on Cold

ROOFS, MOISTURE DETECTION, FREEZE THAW CYCLES, DAMAGE, THERMAL EXPANSION, THERMAL EFFECTS.

SION, THERMAL EFFECTS.

During 1984 and 1985 airborne infrared roof moisture surveys were conducted of membrane roofs at army installations in Alaska. Many of these roofs were also visually inspected and cored to verify infrared findings. Numerous areas of wet invulation were found but often they were small enough and the surrounding roofing system was in good enough condition to warrant removal and replacement of just the wet areas. Essentially all moisture entered from the exterior through flaws in the membrane and flashings. The lack of problems from internal moisture indicates that current vapor retarders, even though imperfect, are adequated some "cold regions" appurtenances such as membrane control joints, and insulation breather vents appear to do more harm than good. The protected membrane (upside-down) roofing system is well sunted to Alaska but some problems have occurred when the membrane lacks slope to drain. Low strength concrete pavers used for roof ballast have been deteriorated by freeze-thaw action.

CHANICS, FLOODING, COUNTERMEASURES.

The upper one-third of the Delaware River is characterized by a steep gradient with a general infle/pool sequence. Due to seasonal low flows, a considerable volume of ice is generated and transported throughout the winter months During February 1981 a catastrophic breakup ice jam occurred along a reach of the Delaware River near Port Jervis, NY, causing \$145 million in damages In February 1982 another breakup ice jam occurred at the same location, causing much concern but minimal flording and damages These events prompted the Philadelphia District, US Army Corps of Engineers, to conduct an investigation of the Upper Delaware River to determine if some form of ice control structure could be implemented in order to reduce ice jam-induced flooding This paper focuses on the field investigations and analyses performed by the US Army Corps of Research and Engineering Laboratory for the Philadelphia District during the period 1983-1985. The study included both on site and remote monitoring of ice conditions and hydraulic analysis of several ice control structure alternatives

Several kinds of flyssh are found in acid snow by scanning electron microscope examination

Flyssh particles from coal fired electric power plants in Fairbanks, Alaska, were found to be spherical or irregular in shape with a 0.2 to 50 micron diameter, and were rich in calcium, siltoon, aluminum and iron

Fly Hof 35 snow samples in Fairbanks ranged from 560 to 748

The acid snow was changed to alkaline snow by dry failout of calcium-rich flyssh from the electric power plants, which were using calcium-rich Alaskan coal

ICE ACCRETION UNDER NATURAL AND LABORATORY CONDITIONS.

Laboratory Combittons. Itagaki, K, et al, 1985, Vol.6, Symposium on Snow and Ice Processes at the Earth's Surface, Sapporo, Japan, Sep. 2-7, 1984. Proceedings, p.225-228, 13 refs. Lemieux, G.E., Bosworth, H.W. 40-2351

40-2351 AIRCRAFT ICING, ICE ACCRETION, WIND TUNNELS, UNFROZEN WATER CONTENT, TEMPERATURE FACTORS, HUMIDITY, PRO-PELLERS.

To compare results of icing studies conducted in wind tunnels To compare results of icing studies conducted in wind tunnels with natural icing conditions, a series of rotor icing studies were mach on top of Mt Washington, New Hampshire The results indicated that considerable differences exist between the two under conditions of similar liquid water content and temperature. The wet-to-dry growth transition temperature, for instance, with comparable temperature and liquid water content, may be more than 10 C higher under natural conditions than in wind tunnel studies. The possible cause of such discrepancies was found to be the vapor saturation existing in most laboratory experiments. The transition existing in most laboratory experiments. The transition comperature of ice accretion measured in natural fog on board an aircraft agreed better with the results of the Mt Washington study.

TURE GRADIENTS, TESTS.

When subjected to a sustained temperature gradient in the presence of monsture in laboratory wetting tests, urefinance and expanded polystyrene roof invulstions accumulate enough moisture to reduce their invulsting ability significantly. Extruded polystyrene is quite resistant to moisture in such tests. But the vapor drive is not as great in actual roofs, and it may reverse direction, thereby seasonally drying the insulation. To determine how well the laboratory tests could predict the wetting rate of invulation in actual protected membrane roofs, extruded and expanded polystyrene and urethane insulations were installed in a protected membrane roof, extruded and expanded polystyrene and it still retained expensively accumulated in invulsting ability. Moisture progressively accumulated in 16-kg cum (1-b cu (t) and 30 kg cum (1-9-lb cu (t) expanded polystyrene invulations, and at the end of the text they retained only about 30 and 40°, of their initial thermal resistance, respectively. The urethane accumulated enough moisture to reduce its insulating ability to about 30°, of its dry value. The laboratory tests provided a valuable indication of the potential long-term moisture gain of these invultions when installed in protected membrane roofs in cold regions.

40-2011 ICE COVER STRENGTH, MILITARY RE-SEARCH, PROJECTILE PENETRATION, IM-PACT STRENGTH, FLEXURAL STRENGTH, BRITTLENESS, PENETRATION TESTS.

BRITTLENESS, PENETRATION TESTS.
Exploratory tests of ice penetration were made by driving small blunt cylinders into semi-infline ice at normal incidence. Three types of laboratory tests were made (1) drop-weight impact (impact speed 1 4-3 1 m/s), (2) high-speed ballistic penetration (impact speed 83-434 m/s), (3) deep penetration at low speed (0 42-4 23 m/s). Penetration by indenters and projectiles could be characterized by the energeties of the process, with little variation of specific energy as penetration speed changed by orders of magnitude. For blunt penetrators entering ice at -5 C, specific energy was typically in the range 15-15 MJ/cu m. Low speed tests provided data on penetration force (and energy) as a function of displacement. The test results were compared with other published laboratory data, and with field tests results for bigger projectiles. pigger projectiles

STATISTICS OF COARSENING IN WATER-SATURATED SNOW. Colbeck, S.C., Mar. 1986, 34(3), p.347-352, With French and German summaries. 14 refs.

SNOW WATER CONTENT, PARTICLE SIZE DISTRIBUTION, SLUSH, WET SNOW, SATURATION, STATISTICAL ANALYSIS

HON, STATISTICAL ANALYSIS

The particle size distributions in water-saturated snow are distinctly log-normal at all times. The rate of increase of the average volume decreases somewhat with time. Both of these conclusions are contrary to the LSW theory, which should apply to this system. Also, the particles are distinctly spheroidal probably prolate. These discrepancies might be explained by extending the LSW theory to nonspherical particles with interparticle contacts. When normalized to the mean the distribution is invariant with only the mean the mean the distribution is invariant with only the mean with time

ICE CORES, ICE SAMPLING, EQUIPMENT, FREEZING, WATER TEMPERATURE, COMPRESSIVE PROPERTIES.

PRESSIVE PROPERTIES.

This short note describes the equipment and procedures developed to mount end caps on icc-core specimens. The system typically achieves end-plaine parallelism within 0.5 micron/min of specimen diameter (i.e. a total indicator runout of 0.002 in for a 4.0 in diameter specimen). The essential elements of the system are a holder and an alignment fixture. The holder firmly grips the icc core about its circumference by the compression of two series of 0-rings. The alignment fixture clamps the holder to align the icc core precisely with the end caps. To bond the ice to the end cap we form a layer of 0.0 water on the end cap, the water freezes immediately upon contact with the ice and forms a strong intimate bond. To date, this system has been used to install phenolic end caps on 10.16 min diameter cores of saline ice. A somewhat better tolerance was obtained with the aluminum caps, due primarily to the geometric stability of that material under the prevailing

conditions. These specimens have been successfully tested in uniaxial and triaxial compression, and with appropriate end caps the system should be suitable for preparing tension

DAMAGE.
The ice forces generated during continuous crushing of an ice sheet against a cylindrical vertical structure vary with time, according to the resistance offered by ice as it fails and clears from the path of the structure. Small-scale experiments were performed to measure the ice forces by pushing rigid cylindrical structures of different diameters at different velocities through an ice sheet. The dominant frequency of ice force variations, defined as the characteristic frequency, was determined from the frequency spectra of the force records The characteristic frequency plot with respect to the velocity-to-thickness ratio reveals a linear relationship, which implies that the average length of the damage zone is proportional to the ice thickness. On the basis of the data presented here, the average length of the damage zone is about one-third of the ice thickness

WAVELENGTH-DEPENDENT EXTINCTION BY FALLING SNOW.

Koh, G., Feb. 1986, 12(1), p.51-55, 9 refs.

SNOWFALL, LIGHT TRANSMISSION, INFRA-RED RADIATION, LIGHT SCATTERING, VISI-BILITY, WAVE PROPAGATION, PARTICLES.

Wavelength-dependent extinction in the visible and infrared Wavelength-dependent extinction in the visible and infrared regions of the electromagnetic spectrum has been observed during studies of transmission through falling snow. The wavelength dependence was particularly noticeable during periods of light snowfall. Particles comparable in size to the wavelengths were also present during these periods. These particles were assumed to be water droplets, and their extinction cross-sections were determined from Mie scattering calculations. The calculations suggest that these particles were responsible for the wavelength-dependent extinction observed during snowfall

MP 2020 ELECTROMAGNETIC MEASUREMENTS OF MULTI-YEAR SEA ICE USING IMPULSE RA-DAR.

SEA ICE, ICE BOTTOM SURFACE, ELECTRO-MAGNETIC PROPERTIES, ICE STRUCTURE, BRINES, AIR ENTRAINMENT, RADIO ECHO SOIJNDING, DIELECTRIC PROPERTIES, ICE PHYSICS, RADAR ECHOES

PHYSICS, RADAR ECHOES
Sounding of multi-year sea ice, using impulse radar operating in the 80- to 500-MHz frequency band, has revealed that the bottom of this ice cannot always be detected. This paper discusses a field program aimed at finding out why list is so, and at determining the electromagnetic (EM) properties of multi year sea ice. It was found that the bottom of the ice could not be detected when the ice structure had a high brine content. Because of brine's high conductivity, brine volume dominates the loss mechanism in first-year sea ice, and the same was found true for multi-year ice. A two-phase dielectric mixing formuls, used by the authors to describe the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-year ice. This three-phase mixture model was found to estimate the EM properties of the multi-year ice.

WASTE TREATMENT, ARTIFICIAL FREEZING, SOIL FREEZING, FREEZE THAW CYCLES, SOIL POLLUTION, COUNTERMEASURES, WASTE DISPOSAL, ENVIRONMENTAL PROTECTION. DISPOSAL, ENVIRONMENTAL PROTECTION. This paper summarizes a preliminary investigation of the toptential use of ground freezing technology for contaminant immobilization. Freezing and thawing were found to significantly decrease the volume of soil slurry and increase the permeability of soils Frozen metal-contaminated soils climinated metal leaching to groundwater under the site Freezing and thawing soils contaminated with moderately volatile organics significantly reduced the soil concentrations of these organics. Freezing the soil from the bottom apparently enhanced upward movement of the organics to the soil surface where losses occurred by volatilization. The amount lost depended on the mobility of the specific volatile component and was as high as 90% for chloroform, benzene and toluene and as loward staff for textrachlorosthylene. Input to groundwater during freezing and thawing of these organics was much less than the unfrozen (control) freatment. Artificial ground freezing for decontamination of soils and for immobilization of contaminants is now being tested on a larger scale.

WASTE TREATMENT, SOIL FREEZING, ARTIFICIAL FREEZING, WASTE DISPOSAL, SOIL WATER, THERMAL PROPERTIES, LATENT HEAT, ENVIRONMENT PROTECTION, RE-FRIGERATION

FRIGERATION

Ground freezing for hazardous waste containment is an alternative to the traditional and expensive slurry wall or grout curtain barrier technologies. The parameters quantified in this analysis of it include thermal properties, refrigeration line spacing, equipment mobilization and freezing time constraints. The economics of the process is discussed based on the Poetsch method for ground freezing. Vertical drill holes with concentric refrigeration lines are spaced along the desired freezing line. A header or manifold system provides coolant to an interior pipe, with the return line being the outer casing. A self-contained refrigeration system pumps coolant around the freezing loop. Temperature-measuring instrumentation is appropriately placed to monitor the progress of the freeze front.

PRESSIVE PROPERTIES.

An experimental study was undertaken of the total force and local pressure generated during the impact of a vertical cylindrical structure against the edge of an ice sheet. The test structure was an instrumented cylindrical pile that protruded under a massive ram suspended from two cranes in the form of a bifliar pendulum. Measurements were made of impact velocity, total ice force, and pressure at a point on the pile. The dependence of normalized maximum net forces with respect to aspect ratio has the same tiend as that for the crushing failure of an ice sheet against a vertical structure. The results of this study indicate that the instantaneous maximum pressure can be an order of magnitude higher than the unconfined compressive strength of ice.

ICE FLOE DISTRIBUTION IN THE WAKE OF A SIMPLE WEDGE.

The ice floe length and ice floe area were found to follow log normal probability distributions defined by the length average and area average, and corresponding standard deviations.

MP 2039 CONDENSATION CONTROL IN LOW-SLOPE

Tobiasson, W., Moisture Control in Buildings: Workshop proceedings, Sep. 25-26, 1984. Edited by E. Bales and H. Trechsel, Washington, D.C., Building Thermal Envelope Coordinating Council, (1985), p.47-59, 47 refs. 40-3204

ROOFS, CONDENSATION, MOISTURE, VAPOR TRANSFER, AIR FLOW, COUNTERMEASURES BUILDINGS, DAMAGE, CONSTRUCTION MATERIALS, MAINTENANCE. CONSTRUCTION

Excessive moisture can damage wood, metal, and concrete roof decks, cause bituminous membranes to wrinkle, shrink, split, delaminate and blister and significantly reduce the insulating ability of most roof insulations. Low-sloped wood-frame roofs with below-deck insulation have encountered wood-frame roofs with below-deck insulation have encountered a significant number of condensation problems. Few such problems occur for compact membrane roofs without intervening air spaces. Air leakage control probably explains the difference. However, serious condensation problems occur in some compact membrane roofs, particularly in cold regions. For most roofs, upward vapor flow in cold weather is generally exceeded by downward vapor flow in warm weather. Thus, the objective is to install "ir-vapor retarders to reduce winter wetting to an acceptable, level. Ventilation of the space between the membrane and the retarder is also practiced.

ROOF MOISTURE SURVEYS: YESTERDAY, TODAY AND TOMORROW.

Korhonen, C.

ROOFS, MOISTURE DETECTION, THERMAL INSULATION, CONDENSATION, MEASURING INSTRUMENTS.

INSTRUMENTS.

Roof moisture surveys are conducted with nuclear meters, capacitance meters or infrared scanners. Nuclear meters and capacitance meters take readings at the spots on the roof with points spaced from 5 to 10 feet apart. Nuclear meters sense the amount of hydrogen in the roofing system at each spot. Since most dry roofs contain hydrocarbons, they do not give zero readings. When water also is present on the roof, nuclear readings increase since water is part hydrogen. Capacitance meters create an alternating current electrical field in the roofing system below. When there is water in the roof, its dielectric properties change and the reading on the capacitance meter increases. Capacitance meters do not "see" deeply (a few inches at most) into the roofing system. An infrared scanner senses the temperature of the surface of the roof. Wet insulation changes the ability of the roofing system to store and conduct thermal energy, thereby causing changes in its surface temperature which the infrared scanner can detect. Instead of a meter reading, the infrared results are presented as shades of brightness on a video monitor. This qualitative visual image provides information about every square inch of the roof, but the information is more subjective than the numbers generated at grid points by nuclear or capacitance meters.

VAPOR DRIVE MAPS OF THE U.S.A.

Tobiasson, W., et al, Hanover, NH, Cold Regions Research and Engineering Laboratory, 11986, 7p. + graphs, 9 refs. Presented at the ASHRAE/DOE/B-TECC Conference "Thermai Performance of the Exterior Envelopes of Buildings III", Clearwater Beach, ISBN 1088 FL, Dec. 1985 Harrington, M.

THERMAL INSULATION, CONDENSATION, MOISTURE, WATER VAPOR, MAPS, BUILDINGS, METEOROLOGICAL FACTORS, DESIGN CRITERIA, SEASONAL VARIATIONS

CRITERIA, SEASONAL VARIATIONS

The thermal performance of most insulations used in building envelopes will be seriously degraded if the insulation becomes wet Problematic mosture can come from within the building envelope Guidance on when to use "air-retarders" needs improvement. As a step in this direction, weather records have been analyzed and two series of maps have been made that relate the relative humidity within a building to the vapor pressure gradients across the building envelope. Lach map in the first series is for a specific ratio of cold weather wetting potential to warm weather drying potential Each map in the second series is for a specific cold weather wetting potential.

HEAT FLOW SENSORS ON WALLS—WHAT CAN WE LEARN.

Flanders, S.N., 1985, No 885, p.140-149, 10 refs. 40.3226

THERMAL INSULATION. WALLS. TRANSFER. HEAT FLUX, HEAT LOSS, BUILD-INGS. ACCURACY, THERMAL CONDUCTIVI- This paper addresses the validity of employing heat flow sensors (HFSs) on the indoor surfaces of building walls to determine thermal characteristics. It also reports on the results obtained in the field.

Some of the factors affecting HFS measurement accuracy (together with a likely percentage standard deviation attributable to that factor) are percentage standard deviation attributable to that factor) are as follows: (a) the conductivities of HFS and its surroundings (3%), (b) convection mode changing over the sensor, causing a +21% bias (26%), (c) the mismatch of HFS absorptivity with the surroundings (6%), and (d) thermal contact of the HFS with the surface (1%) A propagation-of-errors analysis indicates that the resulting standard deviation of an HFS measurement would be approximately 10% of the mean of the measurements. the measurements.

MEASURING INSTRUMENTS.

The U.S. Army Cold Regions Research and Engineering Laboratory has recently acquired an instrumented vehicle for the measurement of forces at the tire/surface material interface. The CRREL instrumented vehicle (CIV) is equipped with moment-compensated triaxual load cells mounted in the vertical, longitudinal (in the direction of motion) and side directions. In addition, accurate wheel and vehicle speeds and rear exit corque and speed are measured. Modifications to the vehicle (to facilitate the performance of traction and motion resistance tests) include four lock-out type hubs to allow front, rear- or four-wheel drive and a dual brake system for front-, rear- or four-wheel braking. A min-computer-based data acquisition system is installed in the vehicle to control data collection and for data processing, analysis and display. Discussion of the vehicle includes its operation and use for the evaluation of the tire performance and surface material properties of motion resistance and traction.

A large-diameter open-ended coaxial waveguide has been interfaced with a commercially available time domain reflectometry (TDR) unit for field measurements of the dielectric properties of frozen and thawed soils and ice. A core barrel developed by the US Army Cold Regions Research and Engineering Laboratory (CRREL) and modified for use in frozen soil was used to auger an annular slot around which the waveguide fits. Time domain traces of waveforms reflected from the sample-air interface and from a metal short are recorded in the field and later analyzed to give complex dielectric permittivity between 0.05 and 1.0 GHz.

MP 2049 REVERSED-PHASE HIGH-PERFORMANCE LIQUID CHROMATOGRAPHIC DETERMINA-TION OF NITROORGANICS IN MUNITIONS WASTEWATER.

Concentrations of HMX, RDX, TNT, and 2,4-DNT are determined in munitions wastewater. Aqueous samples are diluted with an equal volume of 76/24 (v/v) methanolacetonitrile, filtered through a 0.4 micron polycarbonate membrane, and analyzed by reversed-phase HPLC using an LC 8 column with 50/38/12 (v/v/v) water-methanol-acetonitrile. The method provided linear calibration curves to at least several hundred micrograms per liter. Detection limits were conservatively estimated to be 26, 22, 14, and 10 micrograms/L for HMX, RDX, TNT, and 2,4-DNT, respectively, with corresponding standard deviations of 3.4, 33, 4, and 4.6 micrograms/L up to concentrations of 250 micrograms/L. At hisper concentrations, the percent relative standard deviation values were approximately 2% for HMX and RDX and 4% for TNT and DNT. A ruggedness test involving the major manipulative steps in the procedure indicated that consistent results required glass sample containers, preconditioning of filters, and careful maintenance of sample-to-organic solvent ratio. The method was tested with munition wastewater from several Army ammunition plants and found to perform adequately for load and pack wastewaters, wastewater from HMX/RDX manufacture, and contaminated groundwater.

INTERLABORATORY EVALUATION OF HIGH-PERFORMANCE LIQUID CHROMATO-GRAPHIC DETERMINATION OF NITROOR-GANICS IN MUNITION PLANT WASTEWA-TER.

TESTS.

A reversed-phase HPLC method for the determination of nitroorganic compounds (DNT, TNT, RDX, HMX) in munitions wastewaters was evaluated in a collaborative study line laboratories analyzed four aducous matrices, including groundwater and treated wastewater, which were spiked with the analytes at levels from 30 to 600 microgram/L. Recoveries of analytes were similar regardless of matrix DNT and RDX being recovered quantitatively, and TNT and HMX showing losses of about 5%. Intralaboratory precisions, based on the average of duplicate determinations, were less than 15 microgram/L, which corresponds to 9% relative standard deviation at the average concentration examined Interlaboratory precisions were at most 50% larger than in tralaboratory values. Valid statistical analysis required rejection of about 10% of the data set as outliers. The rationale for applying a variety of statistical evaluations is discussed. trataboratory values Valid statistical analysis required rejection of about 10% of the data set as outliers. AGRICULTURE.
Four mathematical models were evaluated for their ability to describe the fate of introgen (N) in the soil environment. The first model is a general one which accounts for convective-dispersive N transport under transient water flow conditions with active N uptake by plants Model II considers N transport to be only of the convective type, whereas model III considers N uptake as a passive process In contrast, model IV considers N transport under conditions of steady water flow in the convective model (II) and the steady state model (IV) are inferior in describing N flow in the soil system as well as the convective dispersive transport mechanisms must be considered for reliable simulation of N behavior in the soil environment. TURING, STRENGTH, TESTS.

Laboratory tests confirm the accuracy of the compliance equations for wedge-loaded, linearly elastic, double cantilever beam test specimens used for the measurement of fracture energy G(I) but show that there are significant discrepancies with theory in tests on rock specimens of the same design. The dependence of the compliance on the length of the crack in the test specimen is not correctly predicted by theory for the experiments done on rock. The axial load applied to the arms of the double cantilever beam as a result of wedge loading reduces Young's modulus by as much as 44% and decreases the measured elastic anisotropy of specimens of grante. The experiments show that useful measurement of G(I) can be made on rock provided that the Young's modulus used in the determination of G(I) is measured on the same specimen under the same conditions of loading as are used in the fracture experiments

RADAR ECHOES, WAVE PROPAGATION, GLA-CIER ICE, ELECTRICAL RESISTIVITY, AN-TARCTICA—VICTORIA LAND, GREENLAND.

TARCTICA—VICTORIA LAND, GREENLAND. A new technique for measuring the speed of radar waves in polar ice sheets was developed to investigate a previously reported disagreement between the permittivities of laboratory and glacier ice. The technique involves lowering a cylindrical radar target to several carefully measured depths in a borehole and measuring the travel time of a radar wave transmitted from a surface radar unit to the target in the borehole. The experiment was performed at Dome C, East Antarctica, and Dye-3, Greenland, and useable date were collected for target depths between 200 ard 800m. After computing the range to the target along a straight ray path and after correcting the travel time for delays in in the radar receiver, the velocities determined from these experiments were found to be in good agreement with the velocities predicted by Robin's empirical formula. The apparent discrepancy between the permittivity of glacier ice, as measured using the radar wide-angle reflection method, and laboratory ice now seems to be due in large part to signal delay in the radar receiver that was ignored in earlier experiments. (Auth)

RECENT CHANGES IN THE DYNAMIC CON-DITION OF THE ROSS ICE SHELF, ANTARC-

ICE SHELVES, FLOW RATE, RADAR ECHOES, ICE COVER THICKNESS, ANTARCTICA—ROSS ICE SHELF, ANTARCTICA—SIPLE COAST, ANTARCTICA—CRARY ICE RISE.

Variations in the amphitude of radar echoes from the bottom of the grid western half of the Ross Ice Shelf have been analyzed. Contrary to the results of a similar analysis performed for the grid eastern sector of the ice shelf, bands of low signal strength downstream from both Crary Ice Rise and the Siple Coast do not correlate with modern flow lines The difference in direction between the radar bands downstream of Crary Ice Rise and the present velocity vectors and the absence of of a comparable trend farther east suggest to us that the grounding line around Crary Ice Rise retreated within the last 1000 years This hypothesis is reinforced by the observation of several domes and hollows in ice thickness downstream of Crary Ice Rise which are similar to a hollow now located in the wake of the ice rise and a dome of its eastern flank. We interpret this as evidence for a rapid increase in flow around the ice rise which carried downstream for the Siple Coast suggests that there was a regional retreat of the West Antarctic grounding line (Auth.)

MODIFIED THEORY OF BOTTOM CRE-VASSES USED AS A MEANS FOR MEASURING THE BUTTRESSING EFFECT OF ICE SHELVES ON INLAND ICE SHEETS.

ICE SHELVES, CREVASSES, FLOATING ICE, ICE MECHANICS, ANTARCTICA—ROSS ICE SHELF.

Bottom crevasses are fractures that extend upward into floating ice shelves. They form when seawater penetrates the base of the rice shelf and ruptures the rice up to the level at which englacial stresses equal the stress of the seawater. For a freely floating rice shelf, the penetrating level of closely spaced crevasses is estimated at about half the rice thickness. In for an isolated crevasse the level is about pin 4. However, an analysis of the heights and locations of bottom crevases in the Ross Ice. Shelf shows that none of the crevasses approach the predicted limits, perhaps because the existing theory does not include the back stress which is present in bounded rice shelves. By reformulating the theory to include a back stress term, back stress which is present experimentally from radar measurements of crevasse height and rice thickness. The magnitude of back stress (2 bars in the grid northwest corner of the rice shelf) suggests the ce shelf is playing an important role in buttressing the inland ice sheet. (Auth.) Bottom crevasses are fractures that extend upward into floating

SNOWFALL.

This paper describes the SNOW-III-WEST experiment and a related study conducted in the Federal Republic of Germany that was designed to increase the understanding of the effects of winter weather on the performance of electro-optical sensor systems in main battle tanks SNOW-III-WEST was conducted at Camp Grayling, Michigan, during December 1984 and January 1985. Its objectives were to document the performance of the M1 tank EO sensor suite in winter and gather data from threat vehicle EO sensors and M1 tank developmental sensors for use in developing system capability comparisons. To accomplish this, an M1 tank gunners primary sight (GPS) was positioned to view and range to vehicular targets at distances out to 1600 m. The GPS contains a day sight, night sight and laser rangefinder. Other US, and threat EO systems were co-located with the GPS. Day and night sight imagery through the device optics was recorded using video equipment while simultaneous target observations by the sight operator were documented. Detailed measurements were made to characterize important target seene and environmental factors. These included Detailed measurements were made to characterize important target scene and environmental factors. These included meteorological, airborne-snow, scene illumination, and atmospheric transmission measurements, as well as inherent and apparent visible and infrared target/background signature measurements. PM Smoke's personnel response and evaluation system for target obscuration (PRESTO) was used to document the sight operator's target detection responses.

EFFECTS OF SNOW ON VEHICLE-GENERATED SEISMIC SIGNATURES.

Albert, D.G., Sensor Technology Symposium, 4th, Apr. 26-28, 1983. Report. Vol.1: Unclassified papers, U.S. Army Engineer Waterways Experiment Station, Vicksburg, MS, Environmental Laboratory, July 1984, p.83-109, 9 refs. 40-3531

SNOW COVER EFFECT, MILITARY OPERA-TION, SEISMIC SURVEYS, ATTENUATION, ACOUSTICS, SEASONAL VARIATIONS, VEHI-CLES.

CLES.
Vehicle-generated seismograms recorded under summer and winter conditions at Fort Devens, Massachusetts, are analyzed and compared. The data were recorded using three-component geophones located just beneath the ground surface and microphones mounted on tripods 0.3 m tall. Winter data were recorded with a 0.7-m-thick snow cover present at the test site. The 14-track FM field tapes were digitized in the laboratory at a sampling rate of 500 Hz in preparation for filtering and spectral analysis. The filtering effect of the snow cover on the seismic data is striking. Because the acoustic-to-seismic coupled energy is attenuated by the snow, the appearance and frequency content of the recorded ground motion is changed dramatically. Automatic vehicle classification algorithms will have to account for these effects if they are to operate successfully in the presence of snow

FROZEN PRECIPITATION AND CONCUR-RENTLY OBSERVED METEOROLOGICAL CONDITIONS.

TY, DIURNAL VARIATIONS.

This study evaluates statistical data for two or more meteorological parameters, recorded concurrently during the winter. The analysis considers only freezing forms of precipitation, placed into seven categories, and correlated with simultaneously observed atmospheric conditions, such as temperature, humidity and wind speed. Computer tabulated data from 11 years of winter weather for München/Riem, West Gernany, were obtained for the investigation. Typical results are 1) the variations in absolute humidity values that can be expected during periods of fog or ground fog at different air temperatures, 2) the likelihood that freezing rain or freezing drizzle will occur least frequently between 1200 and 1700 hours, and 3) the durinal and monthly air temperatures, relative humidity and examples of the unusual and interesting environmental knowledge that can be gained from available climatic records, similar investigations can be conducted for other sites that have long-term weather records in computer-based files.

FORMATIONS, ROADS.
The Complex Variable Boundary Elerient Method or CVBEM is used to develop a computer model (CVBFR1) for estimating the location of the freezing front in soil-water phase change problems. Because the numerical technique is a boundary integral approach, the control volume thermal regime is modeled with respect to the boundary values and, therefore, the CVBFR1 date entry requirements are significantly less than that ususally required of domain methods such as finite-differences or finite-elements. Soil-water phase change along the freezing front is modeled as a simple balance between computed heat flux and the evolution of soil-water volumetric latent heat of fusion.

MODELING OF ICE DISCHARGE IN RIVER MODELS.

Calkins, D.I. Conference on Frontiers in Hydraulic Engineering, Cambridge, MA, Aug. 9-12, 1983. Proceedings. Edited by H.T. Shen, New York, American Society of Civil Engineers, 1983, p.285-290, 7 refs.

RIVER FLOW, RIVER ICE, ICE MECHANICS, DRIFT, ICE MODELS, HEAT TRANSFER, EXPERIMENTATION, TEMPERATURE EFFECTS, HYDRAULICS, FREEZEUP.

Athermal modeling criterion for the ice discharge in refrigerated physical river models is presented along with laboratory results. Ice production was evaluated for freshwater and for 0.3% and 1% urea concentrations in water. Discharges of 0.0056 and 0.0094 cu m/s were run in the model river at air temperatures of 5, 10 and 15°C. Preliminary results show that as the concentration of urea in the water is increased, the model ice outflow increases. The measured for the present at since within a data has been exemplating. increased, the model ice outflow increases. The measured ice discharge at river outlet and the ice accumulation on the riverbed are both linearly related to the air-water temperature difference. The ice accumulation rate on the riverbed was also found to be a linear function of time. The freshwater flow had a greater bed accumulation rate than urea-doped solutions. A slight increase in model ice production was noted for the higher water flow rates. Proper scaling of the ice discharge through a model reach may require relaxing the heat transfer coefficient scaling law because sufficient ice cannot be generated in the river, and ice must be introduced at the inlet of the model. By changing the urea concentration in the water or using a separate ice production flume, a wide range of values for the input of model ice discharge can be selected. model ice discharge can be selected

METAL ICE FRICTION, SLEDS, ICE SURFACE, ICE FRICTION, ICE DETERIORATION, DYNAMIC LOADS, MODELS, EXPERIMENTATION, STATISTICAL ANALYSIS.

The challenge we have been presented with, to perfect the runners of the U.S. Bobsled Team's sled for the 1988 Winter runners of the U.S. Bobsled Team's sled for the 1988 Winter Olympics in Calgary, requires an understanding of the experimentation performed by other researchers, the conclusions reached, and the limitations of their findings. Most of the ice friction studies to date have been made under more or less idealized conditions. Thus, in the highly dynamic situation of a bobsled or a skier sliding on a rough ice surface, a variety of unknown and disregarded factors may contribute greatly to the friction phenomena. For instance, none of the previous studies addressed the mechanical destruction of the ice surface, though earling or melting a track in the ice could account for most of the frictional energy loss. This paper describes the results of a preliminary study performed using a model sled

RAPHY.

The simulated SPOT data acquired from aircraft over the study site had several radiometric characteristics which would not be encountered in the nadir-looking satellite observations. These differential scene brightness features were removed from the data. The corrected data were used in two studies to assess their information content for water quality assessment and land cover classification. Both studies indicate that the SPOT data are comparable to high altitude color-infrared aerial photography in digital form. The implication for land cover mapping is that techniques developed for LANDSAT MSS will need to be modified to allow for interactive user input and the use of textural and contextual features in automatic digital classification. The results of the water quality analysis point to the potential of the SPOT data for assessing the presence of materials in the light-interactive zone of the water column

CLASSIFICATIONS, AGRICULTURE, UNITED STATES—MINNESOTA—LAC QUI PARLE.

SPOT High Resolution Visible (HRV) simulated data were obtained over Lac qui Parle, Minnesota, to determine their usefulness for mapping wildlife habitat categories associated with Corps projects. Ground truth data were available from photometrpreted wildlife habitat unit maps and the agricultural crop inventory prepared for the summer of 1983. A geometric correction could not be applied to the data set, so only the spectral reflectance quality of the data was assessed. The sample size of 512 x 512 pixels was selected for the analyses. An unsupervised classification land cover map was generated with the Earth Resources Laboratory Application Software package. The classification was successful in discriminating wheat and alfalfa and other uniformly colored areas, but pasture and corn could not be separated. Also, we were not successful in separation of grasslands and legumes. Our results indicated that the 20-m HRV data can be used to photoniterpret wildlife habitat using the false color image, but a digital classification cannot be performed. To obtain a habitat map using the HRV data would require a multitemporal analysis.

The Cazenovia Creek Model is a physical hydraulic model constructed in the 160-fix 80-fi (48.8-m x 24.4 m) refrigerated research area of the Ice Engineering Facility at the U.S. Army Cold Regions Research and Engineering Laboratory located in Hanover, New Hampshire The purpose of the model is to reproduce river ice breakup phenomena for optimizing the design of an ice control structure. The optimal design will delay or ultimately prevent the passage of ice flores, climinating downstream ice jam flooding. The performance of the ice control structure during a simulated breakup is monitored by using an interactive real-time data acquisition system. The data acquisition system is governed by a Hewlett-Packard 9485A desktop computer and enables a rapid analysis of the work because of the real-time monitoring. This paper discusses the model and its method of data collection.

LEVEL, PILE STRUCTURES.

Manne structures frozen into an ice cover are subjected to vertical forces as the ice sheet responds to changes in the water level. Pile-supported, light duty structures are especially unlerable to the uplifting forces, which can extract the piles from the soil, destroying the structure's integrity. To evaluate the parameters that control the magnitude of the uplifting force a laboratory model study was conducted in a refrigerated test basin.

SOIL FREEZING, ANALYSIS (MATHEMATICS), BOUNDARY VALUE PROBLEMS, PHASE TRANSFORMATIONS, CONVECTION, STEFAN PROBLEM, TEMPERATURE GRADIENTS, PIPES (TUBES).

PROBLEM, TEMPERATURE GRADIENTS, PIPES (TUBES).

Boundary integral equation methods are presented for the solution of some two-dimensional phase change problems. Convection may enter through boundary conditions, but cannot be considered within phase boundaries. A general formulation based on space-time Green's functions is developed using the complete heat equation, followed by a simpler formulation using the Laplace equation. The latter is pursued and applied in detail. An elementary, noniterative system is constructed, featuring linear interpolation over elements on a polygonal boundary. Nodal values of the temperature gradient normal to a phase change boundary are produced directly in the numerical solution. The system performs well against basic analytical solutions, using these values in the interphase jump condition, with the simplest formulation of the surface normal at boundary vertices. Because the discretized surface changes automatically to fit the scale of the problem, the method appears to offer many of the advantages of moving mesh finite element methods. However, it only requires the manipulation of a surface mesh and solution for surface variables. In some applications, coarse meshes and very large time steps may be used, r-lative to those which would be required by fixed grid domain methods. Computations are also compared to original lab data, describing two-dimensional soil freezing with a time-dependent boundary condition. Agreement between simulated and measured histories is good.

MILITARY OPERATION, HELICOPTERS, NAVI-GATION, BLOWING SNOW, SNOW COVER EF-FECT, PHOTOGRAPHY, AIR CUSHION VEHI-CLES, DETECTION, COUNTERMEASURES, TESTS

Three sets of helicopter-downwash-produced snow obscuration trials were conducted (two sets on 8 December 1983, one set on 17 January 1984), for a total of 30 individual trials. Both hovering and forward flight patterns were performed. In order to obtain an adequate data base which is relevant to Army scenarios, the planned flight altitudes chosen for the text were for representative flying at low-level or NOE (nap-of-carth) missions and landing. In addition, some text flight trials were directed towards information on "masking" and "unmasking" below and above terrain features or tree tops. Thus the altitudes for the text were primarily restricted to no higher than 50 feet above the surface for forward flights, and 150 feet for hovering. Flights were made perpendicular to the main transmissometer line of sight, or in hovering, vertical take-off and landing modes. Three sets of helicopter-downwash-produced snow obscuration

MENT. Little is known about the response of terrestrial plants to 2,4,6-timitrotoluene (TNT). To assess its effects, yellow nutsedge (Cyperus esculentus L.) was grown in hydroponicultures containing TNT concentrations of 0, 10, and 20 mg/L. The deleterious effects of TNT were rapid and occurred at solution concentrations of 5 mg/L and higher Root grown was most affected, followed by leaves and rhizomes. Root weights were reduced about 95% when grown in the presence of TNT. Plant yields were 54 to 74% lower than the control. The TNT and its metabolites, 4-amino-2,6-dimitrotoluene (4-ADNT), and 2-amino-4,6-dimitrotoluene (2-ADNT), and 2-amino-4,6-dimitrotoluene (2-ADNT), were found throughout the plants. So 4-amino-2,6-dinitrotoluene (4-ADNT), and 2-amino-4,6-dinitrotoluene (2-ADNT) were found throughout the plants. Solutions were continually monitored to ensure that no metabolites were present in solution. Since TNT was the only compound taken up, the metabolities must have formed within the plant. Levels of 4-ADNT exceeded those of 2-ADNT and TNT itself, ranging up to 2200 mg/kg in roots of plants grown in 20 mg/L of TNT. The greatest quantities of all three compounds were found in the rhizomes. Increasing solution TNT levels increased the concentrations and quantities of all three compounds in the plants.

ICE CRYSTAL GROWTH, SOLUTIONS, TEM-PERATURE EFFECTS, FREEZING, DENDRITIC ICE, ANALYSIS (MATHEMATICS).

ICE, ANALYSIS (MATHEMATICS).

A finite element solution for ice-crystal growth in subcooled sodium-chloride solution is presented. The freezing process for aqueous solutions requires simultaneous solution of the heat equation in the solid and a complete transport treatment in the liquid region. The moving ice surface in the simulations is continuously tracked via deformable grids. Heat and mass are conserved exactly in the simulations. Specifying the interface temperature based on the constitutional phase diagram is inadequate due to the disparate interfacial growth kinetics for the A-axis and C-axis of the ice crystal. Herein we apply radiation type boundary conditions on the ice interface which maintain. growth kinetics for the A-axis and C-axis of the ice crystal. Herein we apply radiation type boundary conditions on the lice interface which maintain temperature close to equilibrium along a fast-growth axis, but allow subcooled conditions to prevail along a slow-growth axis. This preliminary report concentrates on problem formulation and one-dimensional verification of the method against analytic solutions. MP 2101

PERFORMANCE BASED TIRE SPECIFICA-TION SYSTEM FOR MILITARY WHEELED

TIRES, MILITARY EQUIPMENT, VEHICLES, DESIGN.

DESIGN.

Most military wheeled vehicles continue to utilize the NDCC tire, despite its extremely low tread life and relatively poor performance. Current tire technology has far surpassed that available when the NDCC tire was designed, yet the Army continues, on all but its newest vehicles, to apply this tire. With such a disparity between the NDCC tire and what is commercially available, and with the potential now to design a tire for numerous specific performance areas, how does the Army determine what tire it should use for a particular vehicle. In answering this question, a working aroun was formed and a new tire specification. areas, now does the Army determine what tire it should use for a particular vehicle. In answering this question, a working group was formed, and a new tire specification was developed. This system is based not on specific design features in as much as is possible, but on entical areas of tire performance. This system takes into account the vehicle's mission profile and the necessity of certain minimum levels of performance for various conditions.

In water of mount diameter taken a got ber with Afferent INDING CONSIDER OF THESE ma. rigidite mere tested under otherwise similar environmental ic no conditions at the summit of Mt. Washington. It was found that the more rotationally rigid (stiffer) wire affected both the mode of ice buildup and showed some capability of deicing itself in moderate wind conditions. The lesser ice buildup on the stiffer wire is apparently related to the suppression of dynamic twisting oscillations in the wire, oscillations which were apparent in the softer wire. The softer wire showed heavier ice buildup with the wire at the center of a cylindrical accretion. The stiff wire showed less ice buildup on the windward side with the development of an elliptical accretion due to semi-static rotation of the wire. Deicing of the stiffer wire apparently took place by breaking of the ice after it slowly rotated into the wind by several possible mechanisms. The increased drag on the ice as it moved into the wind creates a bending moment which apparently exceeded the failure stress of the ice near where it was attached to the wire. The ice fails and drops off the wire and the cycle then repeats itself.

Rime icing and freezing precipitation are of concern to the radio and television broadcasting industry. This paper discusses the results of a study seeking to document the severity and extent of transmitter tower icing and related problems in the northes*ern United States. Information was obtained via mail questionnaire and telephone interviews with eighty-five station owners and engineers concerning 118 different stations. Results show that television and FM broadcasters are seriou by impacted, yet AM operators are, in general, only slightly affected by expected New England icing levels. Combined annual costs for icing protection and leing related repairs averaged \$121, \$402, and \$3066 for AM, FM, and TV stations, respectively. None of the AM stations polled employ any icing protection measures, whereas all the TV stations do.

REVEGETATION, VEGETATION, PIPELINES, INTRODUCED PLANTS, GRASSES, UNITED STATES—ALASKA.

STATES—ALASKA.

The Trans-Alaska Pipeline System for transporting crude oil from Prudhoe Bay to Valdez has recently been completed. The Alaskan Natural Gas Transportation System for transporting gas from Prudhoe Bay to the "Lower 48" is underconstruction. The rights-of xay of both these major pipelines traverse the arctic and subarctic climatic zones, where severe environmental conditions require specialized measures for revegetating disturbed terrain. On the oil wipeline right-of-way an argressive grass seeding and fertilizing program was used for revegetation, while on the natural gas pipeline natural renvasion will be encouraged. These different approaches reflect different management goals and changing technologies as revegetation research progresses in the far north. This paper presents some of the implications of these methods for long-term restoration of disturbed terrestrial areas.

ROOPS, COLD WEATHER CONSTRUCTION
This paper compares in situ measurements of R-values R(e) with R-values obtained from handbook calculations for 19
Army buildings in Colorado, Washington, and Alaska The R-values were measured with heat flux and t..nperature sensors, with data severaged and recorded for several days The handbook calculations rely on borings in the construction, depth probes, boroscope inspection, and as-built drawings. A subjective measure of certainty about the construction reflects the quality of this information. Examination of selected soudy cases indicated that convection is a frequent heat transfer mechanism in fibrous insulation, in both walls and attics. Thermal bridges were also evident from the measurements. Air leakage and moisture were not significant causes of (delia)R. Measurements of R-values were found to be in good agreement with handbook values, where knowledge of the construction is good and where convection and Lermal bridges are not major effects.

HYDROLOGIC ASPECTS OF ICE JAMS.

RIVER.

In this study a method for making long-range forecasts of freeze-up dates in rivers is developed. The method requires the initial water temperature at an upstream station, the long-range air temperature forecast, the predicted mean flow velocity in the river reach, and water temperature response parameters. The water temperature response parameters can be either estimated from the surface heat exchange coefficient and the average flow depth or determined empirically from recorded air and water temperature data. The method is applied to the St. Lawrence River between Kingston, Ontario, and Massena, New York, and is shown to be capable of forecasting the freeze-up data

ICE STRENGTH, PRESSURE RIDGES, CO PRESSIVE PROPERTIES, POROSITY, TESTS.

PRESSIVE PROPERTIES, POROSITY, TESTS.

A recent series of tests on the uniaxual compressive strength of ice samples taken from multiyear pressure ridges allows the testing of several hypotheses concerning the variation in strength, within and between ridges. The data set consists of 218 strength tests performed at two temperatures (5 and -20 C) and two strain rates (001 and 00005/s). There was no significant difference between the strength of the ice from the ridge sails and the ice from the ridge keels when tested under identical conditions. As the total porority of the ice from the sails is higher by 40 percent than the ice from the keels, the lack of a significant difference is believed to result from the large variations in the structure of the ice which occur randomly throughout the cores. A three-level analysis of variance model was used to study the variations in strength between 10 different ridges, between cores located side by side in a given ridge, and between samples from the zame core. In all cases the main factor contributing to the observed variance was the difference within cores. This is not surprising considering the rather extreme local var ability in the structure of ice in such ridges. There was no reason at the 5 percent level of significance to doubt the hypothesis that the different cores at the same site and and the different ridges have equal strength means.

RIVER.

Repetitive surveys and measurements from 1983 through 1986 of the ice-covered Tanana River near Fairbanks, Alaska, have shown that flow occurs in sub-ice channels that are separated by longitudinal bars composed of stratified, partly consolidated frail ice of varying type and distribution in contrast to hanging dams, these frazil bars extend up- and downstream parallel to flow as well as from the base of the ice cover to the bed, and act as lateral walls for the sub-ice channels. Individual sub-ice channels may branch sub-ice channels Individual sub-ice channels may branch and reunitt, thus forming a braided pattern beneath the ice cover Longitudinal frazil bars apparently develop at locations characterized by lower velocities, such as where currents are discreted by irregularities in the bed or in the base of the ice cover.

FRAZIL ICE, ICE MECHANICS, ICE GROWTH, AGGREGATES. GRAIN SIZE, ABRASION. UNITED STATES—ALASKA—TANANA RIVER.

A unique form of frazil ice aggregate, the frazil ice pebble, occurs in large quantities in the Tanana River near Fairbanks, Alaska. Frazil pebbles consist of a mixture of individual Alaska. Frazil pebbles consist of a mixture of individual particles, including other aggregates, which are bound together to form a consolidated, compact mass that is similar in appearance to water-worn stream pebbles. Frazil pebbles have been found incorporated into the ice cover, in transport beneath the ice cover and in frazil deposits. They range in length from less than 5 mm to greater than 150 mm. Internally, grains composing the frazil pebbles do not posses a preferred C-axis orientation, but appear to show an alignment related to grain size and shape.

ANALYSIS (MATHEMATICS).
Utilizing results from diagnostic ice-ocean models of the Arctic, Greenland and Norwegian Seas, physical characteristics and problems related to large-scale ice-ocean modeling are examined. In these models a 14-level baroclinic ocean model has been coupled to a two-thickness level dynamic-thermodynamic sea ice model utilizing a nonlinear plastic ice interaction. Simulations of the ocean (for the Arctic Basin only) without the ice cover, and of the ice without the ocean model, are also done to examine certain physical problems.

MP 2143 COUPLED ICE-MIXED LAYER MODEL FOR THE GREENLAND SEA.

ICE MODELS, ICE WATER INTERFACE, SEA ICE, THERMODYNAMICS, SEASONAL VARIATIONS, HEAT FLUX, CONVECTION, ICE MELT-ING, FREEZING, ANALYSIS (MATHEMATICS), GREENLAND SEA.

GREENLAND SEA.

A thermodynamic coupled ice-mixed layer model, designed to study the seasonal cycle of the ice-ocean interactions in the Greenland Sea is presented. The sea-ice model assumes a constant ice thickness and considers only the variations of ice compactness under the effect of the atmospheric and oceanic heat fluxes. The mixed-layer model predicts the rate of penetrative convection within the water column as a result of both the surface buoyancy flux and the mechanical energy input. The mixed layer is embedded in a three-dimensional primitive equations model which calculates the ocean velocity field and its contribution to the time evolution of the temperature-salinity distribution, and also, following Adamec et al. (1981), helps in describing the pycnocline characteristics at the mixed layer base. The model has been tested without advection of horizontal diffusion through a five-years simulation. The annual entrainment-retreat cycle of the mixed layer is well reproduced together with the advance-decay cycle of the ice cover. The horizontal distribution of the mixed layer depth is in agreement with our knowledge of the effect of an ice cover upon a mainly buoyancy driven oceanic convection.

SEA ICE AND THE FAIRWAY ROCK ICEFOOT. Kovacs, A, et al, Fall 1985, 17(3), p.25-32, 18 refs. Sodhi, D.S., Cox, G.F.N.

41-33/ ICE LOADS, OFFSHORE STRUCTURES, DRIFT, OFFSHORE LANDFORMS, ICE PRESSURE, ICE MECHANICS, SEA ICE, ICE COVER THICK-NESS, PRESSURE RIDGES, BERING STRAIT.

NESS, PRESSURE RIDGES, BERING STRAIT. The information obtained in this study revealed that a massive icefoot appears to form around Fairway Rock each winter. This receoot is the result of ice impinging against the island, failing, and subsequently piling up, forming indges up to 15 m high. The icefoot varies from less than 10 m to over 100 m wide. The slope of the inner ridges averages 33 degrees while the slope of the outer face of the icefoot can exceed 70 degrees. This is apparently the result of nongrounded ice rubble having slumped or been cleaved off. The instructive findings are, as anticipated, that ice rubble formation around a large structure placed in "deep" water will not extend appreciably beyond the width of the structure, and therefore will not add significantly to its effective diameter. In order for this to be so, the submarine slope needs to be relatively steep. At Fairway Rock, it is reasonable to assume that the shallowest submarine slope was at or near the angle of repose of the rock talus.

THEORY OF MICROFRACTURE HEALING IN

Colbeck, S.C., Jan. 1986, 34(1), p.89-95, 12 refs., With French and German summaries. 41-261

ICE CRACKS, REGELATION.

ICE CRACKS, REGELATION.
The thermodynamics of air- and vapor-filled microfractures in ice is described. Simple models of healing are constructed assuming the cracks are aspheroidal. The healing of air-filled cracks is rate limited by vapor diffusion through the learn while the healing of vapor-filled cracks is rate limited by heat flow through the ice. Therefore vapor-filled cracks of less than 5 mm radius and an initial aspect ratio of 1000 can heal to a 1/e decay diurnally. Larger cracks weaken the most, heal more slowly, and are effective longer. A temperature gradient imposed on the ice should accelerate healing, especially in a vapor-filled crack that is oriented perpendicular to the temperature gradient.

MICROSTRUCTURE, ROCKS, TENSILE PROP-ERTIES, FRACTURING, GRAIN SIZE, MINERALOGY, SCANNING ELECTRON MI-CROSCOPY, TESTS, CRACKING (FRACTUR-

ING).

The resistance of rock to tensile fracture may be measured by its fracture energy G(I), which is found to range from 40 to 200 J/sq m in tests on nine types of sedimentary and crystalline rock. Differences in microstructure among the rocks tested are the principal cause of differences in the steady state tested or the principal cause of differences in the steady state value of G(I), in the distance that a crack must advance before steady state fracturing is attained, and in the amplitude of the fluctuation of G(I) that accompanies crack advance. When nearly continuous surfaces of weakness are present, as in the Salem limestone, G(I) is long attained state of the fluctuation of G(I) that accompanies crack advance. When a precisiting, interconnected network of microcracks is exploited by the fracture process, G(I) is large, and steady state is attained only after extended crack propagation. The sensitivity of G(I) to crack speed and the presence of water is low under the test conditions used in all the rocks examined. However, the magnitude of G(I) measured in a given type of rock depends on the configuration of the test specimen and on components of stress near the crack tip that do not influence crack growth in linearly elastic materials. The conditions under which G(I) can be considered a material property are therefore restricted. restricted

POROUS MATERIALS, HEAT TRANSFER, CON-VECTION, FLUID FLOW, HEATING, SLOPE ORIENTATION, ANALYSIS (MATHEMATICS), SATURATION.

2-D finite difference simulations of natural convection in a laterally confined, saturated porous medium show distinctive cell patterns and heat transfer characteristics when the medium cell patterns and heat transfer characteristics when the medium is inclined relative to the horizontal. A perfectly horizontal layer heated from below exhibits the classical Benard type convection cells, while a vertical medium heated on one side forms a single Rayleigh cell Progressing from the horizontal to the vertical one sees an evolution of cell forms, each typically featuring a pattern of cell types which alternate longitudinally along the slope Benard cells rotating in harmony with the Rayleigh forces grow, eventually consuming their weakened counter-rotating neighbors. The latter gradually dimitiash to the status of transition cells between the dominant types which flank them. Identifiable transitions in flow configuration and cell morphology, asuse dramatic changes in the efficiency of transverse heat transfer through the layer. These changes have previously been interpreted only as scatter in experimental data.

PHASE TRANSFORMATIO'S, FREEZING, HEAT TRANSFER, STEFAN PROBLEM, BOUNDARY LAYER, COMPUTER APPLICA-TIONS, TEMPERATURE EFF (MATHEMATICS), MODELS. TEMPERATURE EFFECTS, ANALYSIS

The transfinite mapping technique of automatic mesh generation is used with finite elements to solve for two-dimensional heat conduction phase change on a moving mesh. The governing equation is transformed to account for mesh motion, so that coefficients remain attached to moving nodes. The energy conserving attachment of mesh boundaries to phase boundaries avoids approximation across surfaces of discontinuity, and facilitates application of a physical jump condition there. That condition drives boundary motion, while evolution of the interior mesh is determined from boundar, node motion via tite transfirmite mappings. Analytical and computed solutions compare well for the problem of freezing in a corner. Some limitations of both the mapping scheme and this moving finite element system are identified. In conjunction with the latter, a Von Neumann type analysis of the governing equation is outlined, and approximate relations are developed between Stefan number and a numerical Peciet number based on mesh velocity. The transfinite mapping technique of automatic mesh genera-

SNOW CRYSTAL STRUCTURE, METAMOR-PHISM (SNOW), SNOW WATER CONTENT, FREEZE THAW CYCLES, CLASSIFICATIONS, SEASONAL VARIATIONS.

SEASONAL VARIATIONS.

Snow cover crystals must be classified in a physically meaningful way Previous classification systems are not sufficiently detailed or not based on sufficient knowledge of the physical processes. A new system is proposed based on our current knowledge of the physical processes of metamorphism. As more information about snow metamorphism is developed, the labels attached to snow grains should evolve too. Two levels of classification are proposed here. For practical purposes only a few terms like rounded and faceted are necessary, but for a more complete description a more detailed system is also given. The most basic description given it, the table could be useful to many practitioners, while the more complete description given in the appendix will be necessary for many purposes

PERMATROST PRESERVATION, DRILLING, ENVIRONMENTAL IMPACT, VEGETATION, GROUND ICE, THERMAL REGIME, GROUND THAWING, PERMAFROST THERMAL PROPERTIES, REVEGETATION, THAW DEPTH.

ERTIES, REVEGETATION, THAW DEPTH. Former exploratory dniling sites in the National Petitoleum Reserve—Alaska, are examples of the long-term physical modifications resulting from disturbance of perennially frozen terrain. Camp construction and drilling activities in the late 1940s/early 1950s resulted in disturbances which can be grouped by their first modification to the site and its thermal regime trampling of vegetation, killing the vegetative cover, removal of the vegetation and soil. Removal of the vegetation led to the most extensive modifications at all sites, but the subsequent response to disturbance between sites varied with primarily the most extensive modifications at all sites, but the subsequent response to disturbance between sites varied with primarily four factors (1) ground ice volume, (2) distribution and size of massive ground ice. (3) material properties during thaw, and (4) relief, including progressive changes during thaw, subsidence. Variations in response time resulted from the influence of these factors on the type and activity of degradational processes that ensued. Physical stability is required for growth of vegetation and thermal equilibration, and has taken over 30 yr to attain in ice-rich, thaw-unstable areas. Ice-poor, thaw-stable materials in undrained or low relief areas required an estimated 5 to 10 yr for stability; thaw depth measurements suggest that certain of these areas have also equilibrated thermally

NEW METHOD OF MEASURING THE SNOW-SURFACE TEMPERATURE.

Andreas, E.L., Apr 1986, 12(2), p.139-156, 23 refs

SNOW TEMPERATURE, SURFACE TEMPERATURE, SNOW COVER, METEOROLOGICAL FACTORS, HYGROMETERS, DEW POINT, WATER VAPOR, SATURATION, VAPOR TRANSFER, LATENT HEAT, MEASURING IN-STRUMENTS.

STRUMENTS.

Because a snow cover is so tenuous, measuring its surface temperature is not eas. The surface is ill-defined and easily disturbed; in assive transducers commonly used for other surfaces are, thus, generally inappropriate for snow. We therefore describe a hygometric method of measuring the snow-surface temperature. The advantages are that the method is non-invasive, that its accuracy depends only weakly on the surface structure, and that it is reliable even in bright sunlight. The key assumption is that the air at a snow surface is in saturation with the snow, the dewpoint temperature of air right at the snow surface is thus the surface temperature. Consequently, under a fairly wide range of conditions we can, in effect, measure the surface temperature by measuring the dew-point temperature 10 cm above the surface. We develop a theoretical justification for the hygometric measurement, discuss the meteorological parameters that affect the accuracy of the method, and compare hygometric data with more traditional measurements.

TION, SOIL MICROBIOLOGY

A number of samples of polyvinyl chloride (PVC) well casings used for ground water monitoring that varied in schedule, diamete, or manufacturer were placed in contact with low concentrations of aqueous solutions of TNT, RDX, HMX and 2,4-DNT for 80 days. Analysis indicated that there was more loss of TNT and HMX with the PVC casing than with the glass controls, but that the amount lost was, for the most part, equivalent among different types. A second experiment was performed to determine if these losses were due to sorption or if biodegradation was involved. Several different ground water conditions were simulated by varying salinity, initial pH and dissolved oxygen content. The only case where there was an increased loss of any substance due to the presence of PVC casing was with the TNT solution under nonsterile conditions. The extent of loss was small, however, considering the length of the equilibration period. This increased loss is thought to be associated with increased microbial degradation rather than sorption. than sorption

MP 2172 IN-SITU ASSESSMENT OF TWO RETROFIT INSULATIONS.

Flanders, S.N., ASHRAE/DOE/BTECC Conference (on) Thermal Performance of the Exterior Envelopes of Buildings, 3rd, Clearwater Beach, FL, Dec. 2-5, 1985. Proceedings, Atlanta, GA, American Society of Heating, Refingerating and Air-Conditioning Engineers, 1986, p.32-44, 6 refs.

THERMAL INSULATION, WALLS, HEAT FLUX, HOUSES, MOISTURE METERS, CELLULAR MATERIALS, MEASURING INSTRUMENTS,

RESINS.

Two retrofit wall insulations were the subject of in-situ R-value measurement and economic assessment of their success for energy conservation. Ft Lewis, Washington, installed cellulose fiber insulation in the walls of more than 1000 housing units where moisture potentially presented a problem Ft Monmouth, New Jersey, added an exterior expanded polystyrene foam insulation system to its many concrete masonry buildings. These represent retrofit insulation methods that have yet to be applied to thousands of military frame and masonry buildings. The R-value measurement included the use of thermography, heat flux transducers, thermocouples and data acquisition equipment. Holes bored in walls gave independent confirmation of guomposition of the construction layers. Boroscope inspection of wall interiors and moisture meter readings of framing sought evidence of moisture and confirmation of voids in cellulose insulation Measurements of the same or similar buildings occurred approximately a year apart. The economic assessment employed Department of Army life-cycle cost criteria

ANALYSIS OF SELECTED ICE ACCRETION MEASUREMENTS ON A WIRE AT MT. WASH-

POWER LINE ICING, ICE ACCRETION, ICE LOADS, TRANSMISSION LINES, WIND VELOCITY, MATHEMATICAL MODELS.

VELOCITY, MATHEMATICAL MODELS.

Although numerical models have been developed to predict the increase in load on transmission lines due to atmospheric icing, there are very few data available with which to verify them experimentally. The accretion of ice on a writer is a complex three-dimensional phenomenon involving torsion of the write under the accretion weight, vibration, and breaking of some of the ice. In particular, the Mt. Washington test site used for our experiments experiences strong winds that cause high loads, vibrations, and breaking of ice chunks Load measurements for a few wire-icing events are analyzed to determine the functional relationship between iring load and time, and how this compares with the predictions of some available numerical models. Results indicate that loads for steady icing conditions tend to increase exponentially with time. with time

HUDSON RIVER ICE MANAGEMENT.

ICE JAMS, ICE BREAKUP, RIVER ICE, ICE CON-DITIONS, ICE DAMS, ICE COVER EFFECT, RIVER FLOW, ICE COVER THICKNESS, FLOODING. COUNTERMEASURES. WAVES

An ice management strategy is being developed for a reach of the Hudson River that experienced ice jam flooding during the 1983-84 winter — Preliminary field studies have focused on developing a technique to induce the breakup of an on developing a technique to induce the breakup of an ice cover or ice jam by releasing water from an upstream dam. During these studies, a series of abrupt releases generated long-period river waves of different magnitudes, durations and spacings that caused changes in river level, durations and spacings that caused changes in river level, dividently, and integrity of the rice cover. By monotoring the river e'evalion and ice cover at several locations, we have found that each of these wave parameters affected the response of the ice cover. The steepness of the wave front depends upon the initial river stage and the amplitude of the release, and is an important parameter affecting the stability of the ice cover. The sequence of events leading to breakup of the relatively thin ice cover on the Hudon was identical to that reported for other rivers having different physical characteristics and much thicker ice. These studies have revealed that pulsed releases of a practical magnitude were effective in removing the ice cover from the reach and provided basic data for analysis of river ice cover breakup

MP 2175 COMPUTER INTERFACING OF METEORO-LOGICAL SENSORS IN A SEVERE WEATHER AND HIGH RFI ENVIRONMENT.

TRANSMISSION LINES, WIND FACTORS.

Methods are delineated whereby the outputs of ten different sensors used in a study of wind and ice loading on a cable are protected from Radio Frequency Interference (RFI) and severe weather, and processed for logging on a computer. Twelve separate signals from two types of ice detector, two types of cable load cell (including one tri-alial load cell), a pitot-static anemometer, a wind vane and a thermistor are introduced into a Digital Equipment Corporation MINC-11-23 computer. Four of these signals, which would otherwise be incompatible, are conditioned for acceptance by the computer. The signals represent high-speed, consecutive samplings of rapidly changing parameters at a sampling frequency controlled by an operator. Sampled data are logged on a printout and are transferred to magnetic tape for offisite analyses. These methods operate successfully on the summit of Mount Washington, a location known for its harsh weather, in an environment with poor electrical ground and relatively high radio and television frequency interference.

METEOROLOGICAL AND SNOW COVER MEASUREMENTS AT GRAYLING, MICHIGAN. Bates, R.E., et al, Eastern Snow Conference, 42nd, 1985, (1985), p.212-229, 5 refs. O'Brien, H W

DEPTH.

U.S. Army Cold Regions Research and Engineering Laboratory is currently conducting research programs directed toward determining potential effects of airborne snow, snow cover and various meteorological parameters on electromagnetic systems. These programs required extensive-meteorological and snow cover characterization during the winter of 1982-83 and 1983-84 at Camp Grayling, Michigan, which are summarized in this report. The paper also gives a description and discusses the cold weather accuracy and reliability of the automatic recording systems and sensors employed at the snow experiments. Descriptions are given of snow cover measurement techniques, sensors utilized and their accuracy for providing the physical properties of snow cover backgrounds.

EVALUATION OF THE RHEOLOGICAL PROP-ERTIES OF COLUMNAR RIDGE SEA ICE.

Brown, R L, et al, International Conference on Ice Technology, 1st, Cambridge, MA, June 1986. P ceedings, Berlin, Springer, 1986, p.55-66, 14 refs. Richter-Menge, J A., Cox, G F N. 41-1582

The rheological properties of columnar multi-year ridge ice tested under uniaxial compression at -5C and -20C are analyzed in terms of the material microstructure. Microstructural parameters considered included porosity and grain size. Strain rates were varied from 1 100,000-sec to 1/100 sec. A single integral representation was used to model the uniaxial A single integral representation was used to model the uniaxial material constitutive equation. Results show a definite effect of porosity and strain rate on the mechanical behavior. However, grain size was not found to significantly affect properties, probably because the grain sizes tested for columnar sea, ice were all quite large (d=10 to 40 mm). The theological properties also showd some nonlinearities which have not been observed in nonstaline ice. I mally, a viscoplastic representation is recommended as a formulation which might be better suited for characterizing the properties of sea, see.

REGIONAL AND SEASONAL DISTRIBUTIONS OF LOW PRESSURE WEATHER SYSTEMS IN AND AROUND NORWEGIAN WATERS.

Bilello, M.A., International Conference on Polar Lows, Oslo, Norway, May 20-23, 1986. Proceedings. Edited by M. Lystad and O.G. Houmb, [1986], p.53-66, 5 refs. 41-1799

ATMOSPHERIC CIRCULATION, ATMOSPHERIC PRESSURE, SURFACE TEMPERATURE, WEATHER OBSERVATIONS, WIND (METEOROLOGY), OCEANS, METEOROLOGICAL CHARTS, SEASONAL VARIATIONS, NORWAY.

A North Polar region consisting of most of the Scandinavian countries and the major water bodies surrounding these nations was included in a study on the regional and seasonal distributions of low pressure surface weather systems. The region was divided into six zones approximately similar in area, and surface weather maps for three random years were obtained for detailed analysis of daily occurrences of surface lows that passed through these zones. The survey included the lowest isobaric pressure that identified the low, the intensity of the pressure gradient, the zone (or zones) in which the low and its direction of movement. The results of this comprehensive data set were then summarized and seasonal and regional variations of these lows and their characteristics were obtained. A North Polar region consisting of most of the Scandinavian

Saline ice sle's removed from ice sheets grown in an outdoor pool have been studied and related to the complex relative dielectric permittivity. The valine ice closely simulated Arctic sea ice in its structural and salinity characteristies which were regularly monitored in a number of ice sheets grown during the winters of 1983-1984 and 1984-1985. Insitu transmission measurements at similar frequencies were also made on the ice sheet itself using antennas located above and beneath the ice. The slab measurements were made during warming from -28 C to -2 C on slabs grown during the winter of 1983-1984 (4.75 GHz) and during a warming and cooling cycle over a slightly larger temperature range on slabs grown during the winter, 1984-1985 (4.80 and 9.50 GHz). Results from the two winters are compared and the differences analyzed. The in-situ measurements showed extremely high attenuation for the young (<12 cm) brine-trich ice. Good agreement was found between data for the more desalinated samples and theoretical values predictions.

ed by a previously proposed dielectric mixing model that was modified to account for the brine pocket geometry observed in thin sections, and also by including a bulk conductivity term to account for the observed loss (Auth.

ICE SHEETS, ICE DEFORMATION, ICE STRUCTURE, RADIO ECHO SOUNDINGS, GREEN-LAND-DYE 3.

The deformation of layering into folds is modeled for a linear viscous medium moving over a décollement. Folds are generated by flow variations caused by relief on the décolleare generated by flow variations caused by relief on the décollement, variations in friction, or both. The model is applied to folds forming now in the Greenland ice sheet near Dye 3, for which more complete data are available than for analogous solid earth situations and for which the décollement is at or near the bed. The folds (wavelength 4-8 km) are detected by radio reflection sounding. Measured surface deformation and deformation rate are used with the radar results to test the theory Calculated fold amplitude is only 20% less than that measured, which indicates that the theory is substantially correct. Inversion of the data to calculate basal drag and velocity variations is not helpful for near Dye 3 because many different basal boundary conditions can lead to the observed deformations. MP 2186.

BULK TRANSFER COEFFICIENTS FOR HEAT AND MOMENTUM OVER LEADS AND POLY-NYAS.

Andreas, E L., et al, Nov 1986, 16(11), p 1875-1883. 42 refs

Murphy, B. 41-2220

POLYNYAS, SEA ICE, HEAT TRANSFER, TURBULENT BOUNDARY LAYER, MATHEMATI-CAL MODELS

To develop a unified method for parameterizing the turbulent transfer from open water surrounded by pack ice, a reanalysis

has been made of data reported in the literature on momentum and heat transfer over Arctic leads and polynyas. The neutral stability value of the 10-m drag coefficient, 1 49 X .001, is independent of wind speed and open-water fetch for winds from 1 to 10 m/s and fetches from 7 to 500 m. The neutral stability value of the 10-m transfer coefficient for sensible heat, CHN10, is parameterized with the nondimensional fetch. No compelling reason was found to believe that the bulk transfer coefficient for latent heat is different from CHN10 which implies that horizontal homogeneity may not be a severe constraint for evaluating scalar transfer coefficients. The bulk transfer coefficients actually used in modeling turbulent transfer over leads and polynyas are derivable if the atmospheric stability is known. Lastly, a simple formula is developed for estimating one of the fetch factors from an easily obtainable bulk Richardson number (Auth mod.) (Auth mod.)

MICROWAVE DIELECTRIC, STRUCTURAL, AND SALINITY PROPERTIES OF SIMULATED SEA ICE.

Arcone, S.A., et al, Nov 1986, GE-24(6) (Special issue), International Geoscience and Remote Sensing Symposium (IGARSS '85), Amherst, MA, Oct. 7-9, 1985. [Preceedings], p 832-839, 15 refs. Gow, A.J., McGrew, S.G.

ICE CRYSTAL STRUCTURE, ICE ELECTRICAL PROPERTIES, MICROWAVES, SEA ICE, ICE SALINITY, DIELECTRIC PROPERTIES, ICE PHYSICS.

The crystalline structure, salimity characteristics, and microwave dielectric properties of artificially grown saline ice are presented. The ice was grown in an outdoor pool containing salt water of 23-25 per mill salimity. The structure and salimity profiles of this ice sheet closely simulated those found in arctic first-year sea ice. The complex relative dielectric permitivity of slabs removed from the ice sheet was measured at 4.75 GHz as a function of temperature. The slabs were placed between open-end waveguide radiators, and dielectric properties were calculated from the forward scattering coefficient. The results show both the real and imaginary parts to vary almost in direct proportion to the brine volume with values for imaginary showing more variation, and are compared with the previous work of others on actual sea ice samples The crystalline structure, salinity characteristics, and miactual sea ice samples

VELOCITY, WIND TUNNELS, TESTS

Laboratory tests have been conducted on a full-size commercial thermosyphon in an atmospheric wind tunnel located at the U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire. The test variables were evaporator angle, wind speed and heat transfer rate. The effects on thermosyphon performance of nearby walls oriented parallel, at 45 degrees and at right angles to the air flow direction were also studied. Air speed was varied between 00 and 6 meters per second in ten increments. Evaporator angles were varied from 0 to 6 degrees in 3-deg increments theat transfer rates were varied between 600 and 1500 watts in two increments. The air temperature for all tests was about -17 degrees Celsius. Test results are presented showing thermal conductance of the thermosyphon as a function of wind speed, evaporator inclination angle and heat transfer rate. Heat transfer conductances were determined to increase with increasing wind speed, increase with increasing heat transfer rate. transfer rate

EXACT SOLUTION FOR MELTING OF FROZ-EN SOIL WITH THAW CONSOLIDATION.

Lunardini, V.J., International Offshore Mechanics and Arctic Engineering Symposium, 6th, Houston, Texas, Mar. 1-6, 1987. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1987, p.97-102, 9 refs. 41-2408

The role of snow in the construction of ice bridges is discussed It is shown that it has limited value as a structural reinforcement and then only by adding water and freezing the resulting slurry Equations are presented detailing the energy transier during freezing of a water layer vs a water-snow slurry and the times involved with each Natural ice thickening is inhibited by the insulating property of the snow, but snow can be used effectively as either a leveling or wearing surface. The snow should be of uniform depth and not mounded or windrowed to "void deflecting the ice away from the water surface. Insi would substantially weaken the carrying capacity of the ice bridge The role of snow in the construction of ice bridges is discussed from the water surface. This would sulthe carrying capacity of the ice bridge

CONFINED COMPRESSIVE STRENGTH OF HORIZONTAL FIRST-YEAR SEA ICE SAM-

Richter-Menge, J.A., International Offshore Mechanics and Arctic Engineering Symposium, 6th, Houston, Texas, Mar. 1-6, 1987. Proceedings, Vol 4, New York, American Society of Mechanical Engineers, p.197-207, 30 refs. 41-2422

ICE STRENGTH, COMPRESSIVE PROPERTIES, SEA ICE, ICE CRYSTAL STRUCTURE, STRAINS, TESTS, TEMPERATURE EFFECTS.

A total of 110 first-year sea ice samples from Prudhoe Bay, Alaska, were tested in unconfined and confined constant Bay, Alaska, were tested in unconfined and confined constant strain rate compression. All of the tests were performed in the laboratory on a clossed-loop electrohydraulic testing machine at -10. The confined tests were performed in a conventional triaxial cell that maintained a constant ratio between the radial and axial stress to simulate true loading conditions. Three strain rates (1/100, 1/1000, and 1/100,000/s) and three ratios between radial and axial stress (0.25, 0.50, and 0.75) were investigated. This paper summarizes the field sampling and testing techniques and presents data on the effect of confinement on the compressive strength, initial targent modulus, and failure strain of the ice.

DYNAMIC ANALYSIS OF FAILURE MODES ON ICE SHEETS ENCOUNTERING SLOPING STRUCTURES.

Sodhi, D.S., International Offshore Mechanics and Arctic Engineering Symposium, 6th. Houston, Texas. Mar. 1-6, 1987. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1987. p.281-284, 6 refs

41-2433 ICE LOADS, DYNAMIC LOADS, OFFSHORE STRUCTURES, ICF SOLID INTERFACE, FLOATING ICE, ANALYSIS (MATHEMATICS), ICE COVER THICKNESS, VELOCITY, ICE SHEETS. SURFACE PROPERTIES, ICE DEFORMATION The interaction of a sloping structure with a slowly moving ice sheet usually results in bending failure of the ice. The resulting ice blocks are large in area in comparison to their thickness. However, when the velocity of the moving ice increases, the failure mode changes from bending to shear or crushing, resulting in very small pieces. This phenomenon has been observed both in the laboratory and in the field. As yet, no theoretical treatment has been

presented to explain this transition. In this paper, a theoretical formulation of the problem is presented in which the ice sheet is treated as an ice beam moving against a sloping structure. The resulting differential equation was solved by the finite element method, and the solution is presented in non-dimensional form.

THEORY FOR THE SCALAR ROUGHNESS AND THE SCALAR TRANSFER COEFFICIENTS OVER SNOW AND SEA ICE.

Andreas, E L., Jan. 1987, 38(1-2), p.159-184, Refs. p.182-184.

SNOW SURFACE, ICE SURFACE, ROUGHNESS COEFFICIENT, WIND VELOCITY, SNOW AIR INTERFACE, ICE AIR INTERFACE

Although the bulk aerodynamic transfer coefficients for sensi-ble (CH) and latent (CE) heat over snow and sea ice surfaces ble (CH) and lat.nt (CE) heat over snow and sea ice surfaces are necessary for accurately modeling the surface energy budget, they have been measured rarely. This paper, therefore, presents a theoretical model that predicts neutral-stability values of CH and CE as functions of the wind speed and a surface roughness parameter. The crux of the model is establishing the interfacial sublayer profiles of the scalars, temperature and water vapor, over aerodynamically smooth and rough surfaces on the basis of a surface-renewal model in which turbulent eddies continually scour the surface, transferring scalar contaminants across the interface by molecular diffusion. Matching these interfacial sublayer profiles with the semi-logarithmic inertial sublayer profiles yields the roughess lengths for temperature and water vapor. When coupled the semi-logarithmic inertial sublayer profiles yields the rough-ness lengths for temperature and water vapor. When coupled with a model for the drag coefficient over snow and sea ice based on actual measurements, these roughness lengths lead to the transfer coefficients. CE is always a few percent larger than CH Both decrease monotonically with increasing wind speeds as the surface gets rougher both increase at all wind speeds as the surface gets rougher Both, nevertheless, are almost always between 001 and 0015.

ICE SALINITY, COMPRESSIVE PROPERTIES, ICE STRENGTH, STRESSES, STRAINS, TEMPERATURE EFFECTS, TESTS, ICE CRYSTAL STRUCTURE, ICE MECHANICS, SEA ICE.

STRUCTURE, ICE MECHANICS, SEA ICE.

A series of unconfined and confined constant strain rate compression tests were performed on columnar, saline ice samples grown in the laboratory at three temperatures (-3, -5 and -10 C) and two strain rates (2 1/50 and 1/1000 per s). The confined compression rests were conducted in a conventional trainal cell designed to ramp the confining pressure in constant proportion to the axial stress being applied to the cylindrical sample. The ratio of the confining pressure to the axial stress in our tests was 0.25, 0.50 or 0.75. This paper summarizes the results of these tests and compares them to previously obtained first-year sea ice test data. We also compare the crystal structure of the saline ice grown in the laboratory and naturally occurring first-year sea ice. In general, the structural composition and mechanical behavior of the two ice types are similar, indicating that the results obtained from types are similar, indicating that the results obtained from tests on columnar saline ice grown in the laboratory reflect the behavior of first-year sea ice.

STRAIT.

It is estimated that 84 percent of the ice exiting the Arctic Basin through Fram Strait during June and July 1984 was multiyear ice and that a large percentage of this ice is ridged or otherwise deformed. While freeboard and thickness data, together with salinity measurements on cores, usually sufficed to distinguish between first and multiyear floes, preliminstry identification could usually be made on the basis of snow cover measurements with snow cover being much thicker on multiyear ice. Cores from the top half meter of multiyear floes were generally very much harder and more transparent than cores from first-year floes Age estimates of multiyear floes, based on petrographic and salinity characteristics of cores, did not exceed 4 to 5 years for any of the floes that were observed exiting Fram Strait

A brief review of significant advances in the field of sea ice mechanics in the United States is presented in this paper. Emphasis is on ice forces on structures, as the subject relates to development of oil and gas resources in the southern Beaufort Sea. The main topics discussed here are mechanical properties, ice-structure interaction, modeling of sea ice drift, and oil industry research activities Significant advances in the determination of ice properties are the development of testing necedures to obtain consistent. are the development of testing procedures to obtain consistent results. Using stiff testing procedures to obtain consistent results. Using stiff testing machines, researchers have been able to identify the ting near of tensile and compressive strengths on different parents, e.g., strain rate, temperature, grain size, c-axis openation, porosity, and state of stress (uniaxual or multiaxial). Now reliable data exist on the tensile and compressive strengths of first-year and multivear sea, ice.

TARCTICA—WEDDELL SEA.
Essential sspects of sea are dynamics of the Arctic and Antarctic on the geophysical scale were reviewed and the role of arc dynamics in air-sea-ice interaction was discussed. The review is divided into the following components as a discussion of the momentum balance describing ice drift, b) an examination of the nature of sea ice theology on the geophysical scale, c) an analysis of the relationship between ice strength and ice thickness characteristics, and d) a discussion of the role of ice dynamics in the atmosphere-coccan system Because of the unique, highly nonlinear nature of sea-ice interaction, special attention is given to the ramifications of ice interaction on sea ice motion and deformation These ramifications are illustrated both by analytic solution and by numerical model results. In addition, the role of ice dynamics in the atmosphere-ice-occan system is siscussed in light of numerical modeling experiments, including a fully coupled ice-occan model of the Arctic-Greenland-Norwegian seas

SULATION, THERMISTORS.
This report describes a method for using commercially available thermistors to make *m-situ* thermal conductivity *measurements* with commonly available electronic equipment. The emphasis is on use of a single thermistor to measure threnal conductivities of soils and building insulations. Calibration techniques are explained and examples provided. Limitations on this technique are discussed, including material grain size, amount of material needed for a valid measurement, and temperature stability necessary. Specific examples of the use of this technique are provided for both soil measurements and building material measurements. Data analysis is discussed, including a statistical approach to finding the thermal conductivity in large volumes of material

INTERACTION OF GRAVEL FILLS, SURFACE DRAINAGE, AND CULVERTS WITH PERMA-FROST TERRAIN.

PERMAFROST BENEATH ROADS, CULVERTS, EMBANKMENTS, DRAINAGE, GRAVEL, THERMAL INSULATION, THAW DEPTH, GROUND THAWING, PERMAFROST THER-MAL PROPERTIES.

MAL PROPERTIES.

During the summers of 1981 and 1982, the thaw regime of gravel roads and the performance of culverts were obs.rved in the Prudhoe Bay and Kuparuk River oilfields nathern Alaska. This relatively flat to gently rolling coastal plain is concred by shallow lakes, drained lake basins and interconnecting ice-wedge polygons. Depth of seasonal thaw of the predominantly fine-grained soils is less than 50 cm. The permafrost temperature is about -10 C. A combination of visual frost tube readings and temperature measurements were obtained in the tradbed, in an area immediately adjacent to an insulated culvert, and in areas undisturbed by construction. Gravel roads up to 2 m thick thaw completely

and thaw penetrates into the consolidated active layer. Where cepth of thaw exceeds the thickness of the active layer, ice-rich permafrost begins to thaw. Adjacent to the roads, newly formed surface troughs indicate melting of the underlying ice wedges

Shallow impoundments form on the upslope sides of roads where culverts have not been adequately sited or installed. More standardized practices for culvert placement, installation, and maintenance are desirable to minimize disruption of natural drainage.

MP 2216 EFFECT OF OSCILLATORY LOADS ON THE BEARING CAPACITY OF FLOATING ICE COV-

STRENGTH, OSCILLATIONS, TESTS.

Parked vehicles with running engines, or motor driven machinery, subject an ice cover to a static load and to a relatively small oscillatory force, that is caused by the moving parts. Since for the driving frequencies in question the dominant feature is fatigue of the 1/2 cover, while it is undergoing non-elastic time-dependent deflections, an experimental program was initiated to study this phenomenon by running a series of tests in one of the cold rooms at CRREL. An electronically driven shaker placed on the ice cover was used to simulate the dynamic case. A loading device of the same weight and base shape was used as a static control in the tests. Each test consisted of placing these two objects on an ice cover and recording how their vertical siplacements vary with time, for a fixed driving frequency of the shaker. A comparison of these two curves established the effect of the oscillating force component. Eight tests were conducted. It was found that for urea ice covers and driving frequencies of 1, 10 and 30 Hz (60, 600, and 1800 rpm) the vibrating shaker increased the vertical downward displacements and substantially decreased the time to breakdisplacements and substantially decreased the time to break-through.

TRANSMISSION, SCATTERING.

Acoustical reflection and scattering properties of the underside of undeformed sea ice which was grown in an outdoor pond were studied. Echo amplitude fluctuations of normal incidence sonar pings (100-800 kHz) were measured as the sonars moved horizontally under the ice and accumulated into echo amplitude histograms. The Rice probability density function (PDF) was fit to the data and the resultant statistical parameter was combined with the Eckart acoustical scattering theory to estimate an rm roughness of the water/ice interface to be 0.3 mm. Because the rice thin sections showed the ice to be porous and permeable at the interface with dendrites 0.5 mm thick, it appeared that the dendrites controlled the scattering was of the order 0.05. The low reflection coefficient The low reflection coefficient The low reflection coefficient The low reflection predicted from was of the order 005

(low compared to the 035 value which is predicted from the bulk properties of sea ice) was attributed to the dendritie structure which was porous and permeable at the water/ice interface. From the data and modeling done, scattering, and, hence, echo fluctuations, for normal incidence sonars of various frequencies and beamwidths were also predicted

TEMPERATURE EFFECTS.

The cheapest descing chemical to procure—salt—is one of the most effective freezing point depressants, but it can also be one of the most costly where material degradation results from electiolytic corroson. Damage to pavements, primarily bridge decks and elevated highways, and the high cost of repair or rehabilitation, has spurred the search for effective but non-detrimental descing chemicals. The most promising material is calcium magnesium acetate (CMA) which tests made to date have shown to exhibit little or no corrosion potential, under generally-occurring conditions, and to have an acceptable melting action. The nature of salt action on concrete and characteristics for a chemical to serve as an effective descing agent are reviewed. Also, candidate chemicals other than CMA are discussed. Reserved to improve chemical control of snow and ice, both underway and proposed, is reviewed, and the outlook for reduced damage to structures is assessed.

RECRYSTALLIZATION, ICE CRYSTAL STRUCTURE. ICE DEFORMATION, ICE STRENGTH, ICE CRYSTAL NUCLEI, ICE MELTING, PRES-SURE.

Results are presented of annealing recrystallization in both naturally and laboratory deformed ice. Thin section techniques were used to follow the progress of recrystallization which, in the case of highly compressed ice pellets annealed at -3 C, showed that as soon as any new crystal was nucleated in the deformed ice matrix it retained its lattice orientation over the duration of the recrystallization. Laboratory annealing at ambient pressures of highly deformed, strongly oriented crystal ice from cores deep in the Antarctic. Ice Sheet resulted in growth of very large crystals exhibiting casis orientations very much degraded with respect to the original ice. Textures and fabrics of the same ice annealed at 200 bars confining pressure closely resembled those observed in ice undergoing dynamic (annealing) recrystallization at 190-200 bars overburden pressure near the base of the ice sheet, which at this location in Antarctica was at pressure sheet, which at this location in Antarctica was at pressure

41-3958 ICE CRYSTAL GROWTH, ICE CRYSTAL STRUC-URE, GRAIN SIZE, AIR ENTRAINMENT, BUB-BLES, TESTS

BLES. TESTS

Tests were performed at -1 C evaluate the effects of a free surface and the thickness dimensions of timi sections on the growth of grains in fine-grained, pore-rich, strain free polycrystalline ice of grains in fine-grained, pore-rich, strain for grains occurs when the mean size of grains is more than 15 to 2 times the section thickness. Grain growth in thicker sections was significant for the fact that grain boundary migration, leading to 3-4 fold increases in average grain size, was situally unaffected by the presence of large numbers of bubbles in the ice. Not was there any evidence to indicate any concentrating of bubbles along migrating boundaries. Grain boundary groosing was a characteristic feature of most sections undergoing grain growth. This implies actual migration of grooves during grain growth the fact that the total length of grooves decreased with increasing grain size also implies some process of groove consumption during grain growth. Three dimensional grain growth measurements in bulk samples compared favorably with those obtained from sections two to three times thicker than the mean grain diameter. (Auth.)

MP 2232 CHEMICAL PROPERTIES OF SNOW IN THE NORTHEASTERN UNITED STATES.
Kumai, M., Mar. 1987, 48(3) Supplement, p.(C1)625-

SNOW COMPOSITION, CHEMICAL PROPERTIES, AERCSOLS, AIR POLLUTION, SCANNING ELECTRON MICROSCOPY, SNOWFALL, WIND DIRECTION, X RAY ANALYSIS, IONS, UNITED STATES—NEW HAMPSHIRE—HANO-

VER.

Samples of fresh snow from Hanover, N.H., were found to be slightly acidic, with pH ranging from 3.56 to 5.63, and had electrolytic conductivities in the range 2.52 to 80.0 microS/cm. Snowfalls accompanied by southerly winds from densely populated areas averaged about 3 times higher in hydrogen ion concentration and electrolytic conductivity than snowfalls accompanied by northerly winds from less populated areas. Particles found in fresh snow examined with a scanning electron microscope and an energy dispersive X-ray analyzer were most frequently soil micrals, with some fly ash particles, and occasionally diatoms and pollen. Sulfur-rich black particles were presumed to be from local oil-fired heating and electric power plants, while suicon-rich fired heating and electric power plants, while sincon-rich fly ash particles were assumed to have originated at distant coal-fired electric power plants.

In early fall 1983 the Federal Aviation Administration (FAA), tunded the U.S. Army Cold Regions Research and Engineering Laboratory (U.S.CAREL) to conduct a study of airport pasements in cold regions of the United States. A U.S.A.C. REIL's request, the American Association of Airport Executives (AAAE) sent a questionnaire to over 325 general aviation arroots in cold regions. The results from over 200 responses were compiled and evaluated and over 20 airport managers were contacted for additional details. Site visitations were made to 36 airports to obtain additional information. The most common pavement problems identified in the study were associated with non-traffic-related phenomena and included (1) pre-existing cracks reflecting through asphalt concrete overlays (2) thermal cracking and (3) longitudinal cracking Most of the airports experienced (1) water pumping up through cracks, and joints in the pavements during spring thaw, or (2) additional roughness due to differential frost heave in the winter, or both problems. Many airport managers reported that debris was generated at cracks during the winter and spring. Pavement problems can often be traced to the evolutionary history of general aviation airports and the lack of consideration for site drainage. Based on the recognition of these problems, several future research programs are identified.

A portable hot-water drilling system has been developed for conducting detailed thickness surveys of multi-year sea ice. Primary components of the system are a propaneired water heater and a twin-piston pump which is driven by a small gasoline engine. When assembled, the system fired water heater and a twin-piston pump which is driven by a small gasoline engine. When assembled, the system is mounted on a sled which can be moved across relatively smooth ice surfaces by two persons. The system components easily fit inside a BEII 205 or 212 helicopter for movement to other locations. A field program in April and May 1986 proved the viability of the system for rapidly penetrating multi-year sea ice in relatively cold amhient temperatures. The prototype drill penetrated ice at a tes of 3 m/min A 43-cm-diameter ring can be quickly substituted for the normal drilling probe. This ring is useful for making larger holes through the ice for the release or recovery of instruments. Overall performance of the drilling system was highly satisfactory during the field investigations. Future systems, however, will incorporate fuel oil burners and higher-pressure pumps to achieve higher penetration rates as well as to take advantage of more readily available fuel sources. sources

RIVER WAVE RESPONSE TO THE FRICTION-INERTIA BALANCE.

Ferrick, M.G., et al. National Conference on Hydrau-lic Engineering, Williamsburg, VA, Aug. 3-7, 1987. Proceedings, New York, American Society of Civil Engineers, 1987, p.764-769, 2 refs.

OCEAN CURRENTS, SEA ICE, ICE WATER INTERFACE, MATHEMATICAL MODELS

TERFACE, MATHEMATICAL MODELS
A coupled tee-occan model sutable for simulating tee-occan circulation over a seasonal cycle is developed by coupling a dynamic thermodynamic sea see model with a multilevel baroclinic ocean model. This model is used to investigate the effect of ocean circulation on seasonal sea ice simulations by carrying out a simulation of the Arctic, Greenland and Norwegian seas. The ocean model contains a linear term that damps the ocean temperature and salimity towards climatology. The damping term was chosen to have a three-year relaxation time, equivalent to the adjustment time of the pack ice. No damping, however, was applied to the uppermost layer of the ocean model, which is in direct contact with the mo-ing pack ice. This damping procedure allows seasonal and shorter time-scale variability to be simulated in the ocean, but does not allow the model to drift away from ocean climatology on longer time scales. For the standard experiment, an initial integration of five years was performed at one-day time steps and a 145 deg by

1 45 deg resolution in order to obtain a cycle equilibrium. For comparison, a five-year simulation with an ice-only model, and shorter one-year sensitivity simulations without surface salt fluxes and without ocean currents, were also carried out. Input fields consisted of climatological surface air temperatures and mixing ratios, together with daily geostrophic winds from 1979 Operational features of the model are winds from 1979 Operational features of the model are described and an analysis is given in terms of the advance and retreat of the ice edge, ice melt fluxes, heat transport and atmospheric heat balance. ICE CORES, ICE SALINITY, ICE COMPOSITION, ICE SHELVES, ICE PHYSICS, ANTARCTICA— MCMURDO SOUND.

During the austral summers of 1976-77 and 1978-79, several ice cores were taken from the McMurdo Ice Shelf brine zone to investigate its thermal, physical, and chemical properzone to investigate its thermal, physical, and chemical properties. Chemical analyses of brine samples from the youngest (uppermost) brine wave show that, except for the advancing front, it contains sea salts in normal sea-water proportions. Further inland, deeper and older brine layers, though highly saline (\$>200 per mill), are severely depleted in (\$O4)2-Na+ ratio being an order of magnitude less than that of normal sea-water. Consideration of the solubility of alternative salts, together with analyses of Na+, K+, Ca2+, Mg2+, (\$O4)2-, and C1- concentrations, shows that the sulfate depletion is probably due to selective precipitation of mirabilite, Na2SO4 10H2O. The location of the inland boundary of brine penetration is closely related to the depth at which the brine encounters the firm/ice transition. However, a small but measurable migration of brine is still occurring in otherwise impermeable ice, this is attributed to eutectic in otherwise impermeable ice, this is attributed to eutectic dissolution of the ice by concentrated brine as it moves into deeper and warmer parts of the McMurdo ice Shelf (Auth)

MP 2240 PHYSICAL PROPERTIES OF SUMMER SES

ICE IN THE FRAM STRAIT. Tucker, W.B., et al, June 30, 1987, 92(C7), p 6787-6803, 37 refs

SALINITY, ICE CRYSTAL STRUCTURE, SEA-SONAL VARIATIONS, FRAM STRAIT.

The physical properties of sea ice in the Fram Strait region of the Greenland Sea were examined during June and July 1988 in conjunction with the Marginal Ice Zone Experiment field program Most of the ice sampled within Fram Strait during this period was multiyear. Thicknesses and other properties indicated that none of the multiyear ice was older than 4 to 5 years. Snow cover on the multiyear ice was older than 4 to 5 years. Snow cover on the multiyear ice averaged 29 cm, while that on first-year ice averaged couly 8 cm deep. This difference may be related to enhanced sublimation of the snow on the thinner first-year ice. The salinity profiles of first-year ice clearly show the effects of ongoing brine drainage in that profiles from cores drilled later in the experiment are substantially less saline than earlier cores. This section examinations of crystal structure indicate that about 75% of the ice consisted of congelation ice with typically columnar type crystal structure. The remaining 25% consisted of granular ice with only a few occurrences of snow ice. The granular ice with only a few occurrences of snow ice. The granular ice with only a few occurrences of snow ice. The granular ice consisted primarily of frazil, found in small amounts at the top of flocs but mainly observed in multiyear ridges. The horizontally oriented crystal cases showed various degrees of alignment ranging from no alignment to strong alignments in which the alignment direction changed with depth, implying a change in floe orientation with respect to the ocean current at the ice-water interface during ice growth. Evidence of crystal retexturing was observed in the upper meter of nearly every multiyear core. This retexturing, consisting of grain boundary smoothing and nearly complete obliteration of the ice platelet-brine layer substructure, is attributed to summer warming.

MESOSCALE SEA ICE DEFORMATION IN THE EAST GREENLAND MARGINAL ICE

ICE EDGE, ANALYSIS (MATHEMATICS)
In this paper, mesoscale (10 km) are kinematics data obtailed during the drift phase of the 1983 Marginal ke. Zone Experiment are analyzed. The measurements were made with a microwave transponder system accurate to better than 1 m. From the point of view of granular media theory, the nee pack was close to ideal. Over the scale of the array the pack was quite regular, with flores of relatively uniform size closely packed together. The main external

driving force for the ice was the ocean current. Simultaneous current measurements were made at three of the strain array sites. The ice behaved in a relatively rigid manner, with more shear than dilatation occurring. Least squares fits of the strain rate tensor showed the deformation field to be quite homogeneous. Superimposed on the rigid motion were smaller fluctuations with a spectrum falling off proportional to frequency to the power of -3/2 to -2. Close examination of individual strain lines showed rather discontinuous distance changes more representative of plastic slip rather than floe bumping. Although a substantial signal at the inertial period was present in the absolute drift, no clear peaks at this period occurred in the spectra of the strain rate tensor invariants. Analysis of the spatial variation of the underlying ocean currents revealed quite a different picture from that of the ice kinematics. In particular, the current from that of the ice kinematics. In particular, the current form that of the ice kinematics. Overall, the rigid interactive character of the compact ice cover prevented most of the differential ocean currents from being transferred to the differential ocean currents from being transferred to the differential ice inotion. differential ice motion

ROLE OF FLOE COLLISIONS IN SEA ICE RHEOLOGY. Shen, H.H., et al, June 30, 1987, 92(C7), p.7085-7096,

21 refs. Hibler, W.D., III, Lepparanta, M.

ICE MECHANICS, ICE FLOES, ICE EDGE, ICE DEFORMATION, STRESSES, RHEOLOGY, MATHEMATICAL MODELS, PACK ICE

MATHEMATICAL MODELS, PACK ICE.

A collisional rheology for an idealized two-dimensional flow of a fragmented ice field is derived. This fragmented ice field is modeled as an assembly of identical smooth disks. Collisions between neighboring disks are caused by the mean deformation field. These collisions transfer momentum which produces the internal stresses in the deformational energy, a relationship between the stress and strain rate is quantified. To demonstrate the essential idea, an analytical derivation is first given under quite restricted assumptions. A Monte Carlo simulation is then developed to provide a more general approach for the analysis. It is found that the collisional stresses are proportional to the square of disk diameter and the square of the deformation rate. The magnitude of stresses is also found to increase rapidly as the collisional restitution of disks increases. The collisional rheology yields zero tensile strength. The associated normal flow rule commonly used in the plastic. collisional rheology yields zero tensile strength, sociated normal flow rule commonly used in the plastic rheology is not valid in the collisional rheology. It is found that the collisional stresses are very small conse-

iound that the collisional sitesses are very small Consequently, the resulting stress divergence is estimated to be much lower than the air stress typically encountered in the marginal ice zone become singular as the maximum compactness is reached, indicating that a different mechanism may exist in that

TRAILING-TIRE MOTION RESISTANCE IN SHALLOW SNOW.

Blaisdell, G.L., International Conference of ISTVS, 9th, Barcelona, Spain, Aug. 31-Sep. 4, 1987. Proceedings, Vol.1, Hanover, NH, International Society for Terrain Vehicle Systems (ISTVS), [1987], p.296-304, 6 refs.

SNOW STRENGTH, TRAFFICABILITY, VEHI-CLES, SNOW COVER, GROUND THAWING, TIRES, SNOW COMPACTION, VELOCITY, TIRES, TESTS.

Considerable attention has been given to the subject of motion resistance of tires traveling in virgin snow. Trailing tires (those that follow in the rut of a preceding wheel) are generally assumed to provide negligible motion resistance. Levels of resistance for trailing tires were measured with the CRREL Instrumented Vehicle operating in two snow conditions. Using this vehicle, two methods of measuring trailing tire resistance have been explored. Good agreement was found between the methods. A very different balance of leading-tire to trailing-tire resistance was also found for two snows. For both snows, it is seen that it is not appropriate to assume that trailing-tire resistance is negligible. e attention has been given to the subject of motion f tires traveling in virgin snow. Trailing tires

TURBULENT BOUNDARY LAYER, SNOW SUR-FACE, SNOW AIR INTERFACE, WIND VELOCI-TY, AIR TEMPERATURE, HUMIDITY.

TY, AIR TEMPERATURE, HUMIDITY.

Time series were measured of the turbulent fluctuations in longitudinal (u) and vertical (w) velocity and in temperature (t) and humidity (a) with fast-responding sensors in the near-neutrally stable surface layer over a snow-covered field. These series yielded individual spectra, u-w, w-t, w-q, and ey cospectra, and phase and coherence spectra for nondimensional frequences (Iz/U) from roughly 0.001 to 10. This, thus, one of the most extensive spectral sets ever collected over a snow-covered surface. With the exception of the u-w cospectra, all of the spectra and cospectra displayed the expected dependence on frequency in an inertial or inertial-convective subrange. At this complex site, turbulence alone determines the spectra and cospectra at high frequency, while at low frequency, the spectra and cospectra reflect a combination of topographically generated turbulence and, probably, internal waves. From the measured temperature and humidity spectra and the t-q cospectra, refractive index spectra for light of 0.55 micron and millimeter wavelengths were computed, the first such spectra obtained over snow. From the u, t and q spectra, the surface sensible (Hs) and latent (Hl) heat fluxes were estimated using the inertial-dissipation technique. Aspects of these computed and estimated values are discussed. (Auth, mod.)

OPTICAL PROPERTIES OF ICE AND SNOW IN

THE POLAR OCEANS. 1. OBSERVATIONS. Perovich, D.K., et al, 1986, Vol.637, Ocean optics 8. Edited by M A. Blizard, p.232-241, 38 refs. Maykut, G.A., Grentell, T.C.

ICE OPTICS, SNOW OPTICS, SEA ICE, BRINES, ALBEDO, SCATTERING, ICE SPECTROSCOPY, ICE COVER EFFECT, TEMPERATURE EF-FECTS.

FECTS. Optically sea ice is a complex material with an intricate and highly variable structure which includes brine pockets, air bubbles, brine channels and internal platelet boundaries Large variations in the optical properties of the surface layer can occur on horizontal scales of only a few meters, complicating efforts to quantify larger scale interactions between shortwave radiation and the ice-occan system. Radiative transfer in sea ice is dominated at visible wavelengths by scattering rather than absorption. Because scattering in the ice is essentially independent of wavelength, spectral variations in the optical properties are primarily the result of differences in absorption. Observations show that albedos are particularly sensitive to the presence of liquid water in the surface layers, the effect being most pronounced at wavelengths above 600 nm. Albedos and extinction coefficients in the ice vary inversely with brine volume, and wavelengins above oou nm. Albedos and estinction coefficients in the ice vary inversely with brine volume, and thus temperature. Below the eutectic point, precipitation of solid salts causes a sharp increase in scattering and corresponding increases in albedo and absorption. Biological sponding increases in albedo and absorption biological activity in natural sea ice often affects light transmission and absorption, particularly in coastal regions and in the southern ocean Phase function measurements indicate that the seattering distribution in sea ice is only weakly dependent on wavelength and brine volume

OPTICAL PROPERTIES OF ICE AND SNOW IN THE POLAR OCEANS. 2. THEORETICAL CAL-CULATIONS.

TEMPERATURE EFFECTS, GRAIN SIZE.
Radiative transfer models of sea i.e applied to date range from a simple Bouquere-Lambert representation for net downwelling irradiance through 16 stream models which takes into account detailed variations in ice microstructure. Both sea ice and snow are strongly multiple scattering media with single scattering albedos well above 0.9 through the visible and into the near infrared. Parameter studies indicate that the optical properties of sea ice are controlled by the density of brine and vapor inclusions which in general undergo substantial seasonal changes. Melting and brine draining are the principal causes of these variations. For ice below 5.0, temperature effects are relatively weak unless the

T(ice) drops below the eutectic point of snow depend primarily on grain size, the bulk density, and the presence of impurities such as carbon soot. The theoretical models appear to be able to reproduce observations quite well and have revealed that soot or dust contamination of snow appears to be prevalent even in the Arctic snow appears to be prevalent even in the Arctic.

OPTICAL CHARACTERIZATION OF SEA ICE STRUCTURE USING POLARIZED LIGHT TECHNIQUES.

DRE.

Optical properties of sea ice depend to a greater or lesser extent on its crystalline properties and on the size, shape, and distribution of brine inclusions systematically trapped in the ice crystals. The use of polarized light techniques was demonstrated to examine the internal structure of sea ice. Using both naturally occurring and laboratory simulated sea ice we show how the crystalline and salinity components originate including discussion of the mechanisms by which first-year ice desalinates and recrystallizes into multi-year ice exhibiting optical properties significantly different from those of first-year ice.

BUTION.

The most common quantitative measurement of falling snow is the precipitation rate. The time resolution of conventional mechanical snow gauges is poor, and their accuracy in measuring light snowfall is severely limited. An optical device designed to give an accurate instantaneous measurement of rain rate has been modified to operate in falling snow. Snow rates are inferred from statistical averages of intensity fluctuations caused by snow particles as they fall through a beam of light. Test results snow that the optical device is catternely sensitive to light snowfall and may be a significant improvement over mechanical techniques to measure snow precentiation rates. precipitation rates

MP 2260 ANALYSIS OF 112 YEARS OF ICE CONDI-TIONS OBSERVED ON THE OHIO RIVER AT CINCINNATI.

TERWAYS), UNITED STATES—OHIO RIVER.

Daily tee conditions observed on the Ohio River at Cincinnation the winters of 1874-75 through 1985-86 were analyzed. The amount of tee on the river, except during particularly cold winters, has decreased since 1900. The decline has been especially significant starting around 1930. Investigation of the secenty of seea winter, using the number of freezing degree-days as an index, revealed no systematic temperature trends over the 112 years of recont. Associations between number of days with river tee and concurrent accumulated freezing degree-days over ,0- or 11-winter increments were investigated. The results showed that between the winters of 1934-35 and 1963-64 considerably more freezing degree-days were required to produce tee, but the trend has reversed slightly since then. This decreasing trend in observed tee has occurred during a period of basin development, as indicated by a sample population, the construction of large locks and dams, and an increase in nasigation tonnage on the trier. The increase in heated discharge into the river corresponding with baun development and the construction of large locks and dams have probably had the most significant impacts.

ALCOHOL CALORIMETRY FOR MEASURING THE LIQUID WATER FRACTION OF SNOW.

SNOW WATER CONTENT, TEMPERATURE MEASUREMENT, SNOW ICE INTERFACE, UNFROZEN WATER CONTENT, CALORIMETERS, LATENT HEAT, ICE VOLUME, SPECIFIC HEAT, MEASURING INSTRUMENTS.

MEASURING INSTRUMENTS.
Equipment and procedure have been devised for measuring the liquid water/ice ratio of snow. The measurement is based on the temperature depression observed on dissolving a 25 g snow sample at 0 C in 80 g methanol at 0 C. The masses of the sample and alcohol are held constant, and the heat of solution of 25 water in 80 g methanol at zero deg is constant, so the or / variable is the water/ice ratio in the sample. The solution process occurs quickly enough that it is essentially adiabatic. The latent heat ratio in the sample. The solution process occurs quickly enough that it is essentially adiabatic. The latent heat of fusion of up to 8.3 g ice is supplied by the heat of solution of the water in the alcohol. The heat of fusion of any sce above 8.3 g is supplied by a decrease in the solution temperature. Since the total latent heat of fusion varies linearly with ice content, and the solution specific heat is virtually constant, the final solution temperature also varies linearly with sample ice content.

WASTE TREATMENT, FOREST LAND, WATER TREATMENT, LAND RECLAMATION, IRRIGATION, COST ANALYSIS, MAINTENANCE.

TION, COST ANALYSIS, MAINTENANCE.
Land treatment of menicipal wastewater on forest land has been practiced experimentally for over twenty years and on a full-scale basis for over ten. The technology of land application consists of sprinkler systems have been installed in existing forests using either buried or aboveground laterals. Desing guidance for sprinkler spacing and operating pressures for solid-set systems in forests is presented. Costs of installed forest land application systems are also given. Costs and design factors are reviewed for systems at Snoqualniic Pass, Washington; Wolfeboro, New Hampshire; Lake of the Pines, California; Clayton County, Georgia; West College, Pennsylvania. Operation and maintenance costs are provided for systems at Clayton County, Georgia; West Dover, Vermont, and Kennett Square, Pennsylvania. Reduction of the cost of future systems can be accomplished by minimizing the amount of effluent storage provided. Most forest systems can operate with thirty days storage or less. New technology and new plantations can allow reductions in the cost of wastewater application. Potential revenue from tree harvest can also reduce overali costs. MP 2267

PHOTOGRAPHY, ICE NAVIGATION.

As part of the Corps of Engineers River Ice Management Program, Landsat imagery and low-altitude video imagery were used to map ice conditions along the Ohio, Allegheny, Monongahela, Illinois, and Kankakee Rivers. The imagery was analyzed using photointerpretation techniques. Landsat imagery was used to map river ice from 1972 through 1984. The video imagery was used from 1984 to 1987. Ice conditions on these rivers can change rapidly, often daily, and the areal extent of ice is typically greatest from mid-Jan to mid-Feb. In spite of the small-scale and limited coverage of Landsat imagery, it is useful for analysis of general river ice conditions, especially during severe winters when ice becomes extensive. Video imagery is an economical means of documenting river ice conditions, although cloud cover, inclement weather, and low ceilings restrict opportunities for more frequent coverage. It also can provide near-real-time data when extreme ice conditions cause navigation emergencies. navigation emergencies.

BASELINE ACIDITY OF PRECIPITATION AT THE SOUTH POLE DURING THE LAST TWO MILLENNIA.

Cragin, J.H., et al, Aug. 1987, 14(8), p.789-792, 38

Giovinetto, M.B., Gow, A J.

ICE COMPOSITION, FIRN, CHEMICAL PROP-ERTIES, ANTARCTICA AMUNDSEN-SCOTT STATION.

Measurements of meltwater pH from annual layers of South Pole firn and ice samples ranging in age from 40 to 2000 years BP show that precipitation at this remote site has a higher natural acidity than that expected from atmospheric

equilibrium with CO2 The average pH of deaerated (CO2-free) samples was 564, while air-equilibrated samples averaged 537, a pH that is about a factor of two more acidic than the expected background pH of 565. The observed "excess" acidity can be accounted for by sulphur and nitrogen cation levels in the samples originating from non-anthropogenic H2SO4 and HNO3 Because of the presence of these naturally occurring acids in South Pole precipitation, a pH of 5.4 is considered a more representative baseline reference pH for acid precipitation studies. SURING INSTRUMENTS, ICE DETECTION.

The accumulation of rime and glaze ice on structures depends on meteorological variables such as wind, precipitation rate, air temperature, fog density and atmospheric moisture content. However, highly accurate measurements of meteorological variables during periods of icing (including wet shows) that occur in the cold regions of the world are for the most part unavailable due to instrumentation failure or geographic remotences. For the last 5 years, USACRREL has been modify:

—csting, and utilizing state-of-the-art sensors and received systems for measuring winter environmental condition.

—paper discusses meteorological sensors (including ice detectors) seed in adverse cold environments, including the mountaingous areas of the northeastern United State. ice detectors, used in adverse cold environments, including the mountar outs areas of the northeastern United States. One of the state-of-the-art site-specific sensor packages, the newly developed Environmental Instruments Model 200 Dual Processor Meteorological System has been thoroughly evaluated during periods of adverse weather and icing. The system has no moving parts, but incorporates two static pair heated resistive sensing elements for measuring wind speed and direction, a platinum resistance thermometer for temperature, and a pressure transducer for atmospheric pressure. Results obtained and problem areas encountered using a number of different sensors in adverse weather conditions at both the CRREL spos-field experiment test sites. tions at both the CRREL snow-field experiment test sites and high elevation winter icing experiment sites are discussed

CIOUD DROPLETS, WEASURING INSTRU-MENTS.

Several seasons of using data have been collected under natural using conditions on the summit of Mt Washington. New Hampshire Two models of the Rosemount Ice Detector were evaluated in the contest of providing using intensity data under various conditions. Average temperature, with speed, liquid water content and median droplet diameter were also recorded for each using event, the latter two parameters being provided by rotating muticipanders. A measure of ising rate has been calculated from the liquid water content and the wind speed, and has been compared to the ice detector cycling rates. For detectors with long heat-on times the upper limit invasumme cycling rates of the detector with long heat-on times also exhibits problems at higher temperatures. At environmental temperatures are freezing, the probe takes considerable time to zool below freezing and begin to again accumulate ice. Thus arisatinum cycle rate is reached under these conditions which can be well below the actual scing rate. Under prolonged scing conditions, see accumulations on the unheated parts of the probe and support structure can interfere with the artflow past the probe, significantly changing the collection efficiency. Under extreme conditions, this can result in a complete lack of cycling. The problems associated with annication Under extreme conditions, this can result in a complete lack of cycling. The problems associated with application of the ice detector cycling rates as a measure of accretion rates on more complex objects are also discussed. In particular, the fact that the collection efficiency is so alrongly dependent on the droplet size distribution may until is

SELF-SHEDDING OF ACCRETED ICE FROM HIGH-SPEED ROTORS.

Itagaki, K., June 1987, No.3439, International Workshop jong Atmospheric Icing of Structures, 2nd, Trondheim, Norway, June 19-21, 1984. Proceedings, Edited by M. Ervik, p.95-100, 18 refs, Includes dis-

NESS, TENSILE PROPERTIES.

Ice accreted on high-speed rotors operating in supercooled fog can be thrown off by centifugal force, creating severe unbalance and dangerous projectiles. A simple force balance analysis indicates that the strength of accreted ice and its adhesive strength can be obtained by measuring the thickness of the accretion, the location of the separation, the rotor speed and the density. Such an analysis was applied to field and laboratory observations of self-shedding events. The results agree reasonably well with other observations. MP 2279

ICE ACCRETION, POWER: INE ICING, TRANSMISSION LINES, WIND PP SSURE, ANALYSIS
(MATHEMATICS), AIR FLOW, COMPUTER APPLICATIONS, ICE FORECASTING, MODELS, SUPERCOOLING

SUPERCOOLING.

A time-dependent computer model capable of predicting the accretion of rime ice on a wire free to rotate is desembed. A finite element technique is used to obtain the air velocity field adjacent to the wire. A local collision efficiency is calculated for several radial sectors of the wire by tracking supercoored water droplets of various sizes until they collide with the wire. The asymmetric buildup of ice causes the wire to rotate, changing the flow field around the wire and the rate of ice accretion. The finite element technique is a very effective method of analyzing this problem because the ice accretion shape is not limited to a simple geometric shape. The drag force is computed as a function of time to investigate the forces acting on the wire during an icing event. Model results are presented including compansions of icing simulations of wires of various rigidities and lengths.

WASTE TREATMENT, WATER TREATMENT, FOREST LAND, LAND RECLAMATION, DE-SIGN, WATER POLLUTION, COUNTERMEAS-LIRES

URES.

An overview of several case studies of forest and treatment with municipal wastewiter in New England is presented. One of the earliest land treatment systems in this area in modern times was installed in 1971 by the state of New Hampshire at Sunapee State Park, in a mature forest of mixed hardwoods and conities. The system is in excellent condition, and continued operation is planned for the foresceable future. Municipal forest land treatment systems are also operating successfully at West Dover Vermont, Wol feboto, New Hampshire and Greenville, Maine. Design and operating information is provided for all 4 systems. For West Dover the energy consumption is evaluated and the treatment performance is documented. West Dover operates thoughout most winters with minimal storage. The improvements in water quality at several of these systems are also discussed and a method for estimating phosphorus removal is described. removal is described

MP 2281 DETECTING UNDERGROUND OBJECT-S/UTILITIES.

Hironaka, M.C., et al, Workshop jong Facilitating Technology Advancement in the U.S. Construction Industry, Austin, TX, Oct. 28-29, 1987. Proceedings, Proceedings. (1987), p 36-43, 3 refs Bigl, S R

UNDERGROUND FACILITIES, DETECTION, RADAR ECHOES, MEASURING INSTRU-MENTS, PENETRATION TESTS

Hand-held detectors and ground penetrating radar systems have been field evaluated to determine their effectiveness in locating underground objects and utilities. The hand-held detectors are limited to locating either metallic or nonmetallic (by radio transmitter) lines and are best suited to tracing such lines. To trace such lines, at least a vague idea of their location must be known or a point of physical access must be available. Ground penetrating radar (GPR), on the other hand, has the capability to detect both metallic and nonmetallic objects without prior knowledge of their presence. However, as presently configured, GPRs have certain deficiencies that resulted in poor performance in field evaluation tests. The best system detected only 60% of the metallic and 36% of the nonmetallic objects that were present in our test site. We therefore have development efforts underway or completed to improve the capabilities of GPRs. These efforts include optimum GPR source signal, high-power focused antinna, and signal processing-image reconstruction software. image reconstruction software.

MP 2282 INFRARED TESTING FOR LEAKS IN NEW ROOFS.

Korhonen, C., Workshop ton; Facilitating Technology Advancement in the U.S. Construction Industry, Austin, TX, Oct. 28-29, 1987. Proceedings, (1987), p.49-54, 4 refs. 42-968

INSULATION, IEMPERATURE VARIATIONS.
Newly constructed roofs can develop leaks as soon as they are built, but these leaks may not manifest themselves insude the building until after the warranty has expired High resolution infrared scanners can be used during the warranty period to locate the wet insulation resulting from these leaks. When combined with detailed visual examination, infrared surveys can help to determine who is responsible for the leak. If the leak is the result of a design or workmanship error, then the building owner is saved the expense of pursuing remedial repairs on a new toof. temedial tenaits on a new tool.

MP 2283 COMPARISON OF SNOW COVER LIQUID WATER MEASUREMENT TECHNIQUES.

Boyne, H S., et al. Oct 1987, 23(10), p 1833-1836, 19 refs.

Fisk, D.J.

SNOW WATER CONTENT, UNFROZEN WATER CONTENT, SNOW MECHANICS, MELTWATER, MICROWAVES, REMOTE SENSING, TEMPERATURE MEASUREMENT, SEEPAGE.

The amount and distribution of liquid water are important for assessing the mechanical strength, meltwater generation, and meltwater transmission in snow. Liquid water also has a profound effect on the performance of active anipassive remote sensing systems operating in the microwave and millimiter wave region of the electromagnetic spectrum. New methods of measuring liquid water have been reported which show considerable promise. Our purpose is to address the question of measurement equivalence by comparing the three direct methods of freezing calorimetry, and didution and by comparing the precision of a calibrated capasitance probe with one of the direct methods. All comparisons were made in a laboratory cold from with snow having a mass liquid water content of 0-14 mlg per 100 mlg of snow. However, the operational achievement of equivalence is strongly dependent on a variety of factors such as sample size, missing of snow and working fluid, and operator skill. The amount and distribution of liquid water are important

ICE FOG, INFRARED RADIATION, ELECTRO-MAGNETIC PROPERTIES, ATTENUATION, PARTICLE SIZE DISTRIBUTION, MATHEMATI-CAL MODELS.

CAL MODELS.

An approximation model is derived for the attenuation of visible and infrared radiation through ice fog. Assuming spherical particles and single scattering, a formula for estimating the extinction efficiency factor has been developed by combining the approaches of Hart-Montroll and Nussenziverg-Wiscombe. With the use of a Maxwell function to describe the size distribution of ice fog particles, a theoretical integration over the distribution, is possible. The resulting extinction coefficient is a function of the mode radius of the distribution, the wavelength of the incident radiation, and the complex refractive index of ice. Its simple formulation provides an efficient means of scaling infrared to visible attenuation.

SENSING.

Snowfall intensities are currently classified by the National Weather Service Meteorological stations as "light, moderate and heavy" using visibility as a criterion. However, snowfall occurs with other obscurants, such as fog, making it extremely difficult to determine the actual snowfall intensity, therefore any enterior dependent on visibility alone should only be used as a guide. This paper presents a more quantitative method of determining snowfall using snow depth accumulation rate (cm/hr) and total hourly water equivalent (mm) is criteria. Intensive snowfall accumulation rates and water equivalent amounts were determined at the SNOW experiments at Fort Ethan Allen, Vermont, during the winters of 1980-81 and 1921-82, and at Camp Crayling, Michigan, during the winters of 1983-84 and 1984-85. These data are used to validate the preliminary snowfall intensity medel are used to validate the preliminary snowfall intensity model

EFFECT OF ICE-FLOE SIZE ON PROPELLER TORQUE IN SHIP-MODEL TESTS.

Tatinclaux, J.C., American Towing Tank Conference, 21st, Washington, D.C., Aug. 5-7, 1986. Proceed-ings. Edited by R.F. Messalle, Washington, D.C., National Academy Press, 1987, p.291-298, 4 refs. 42-1352

ICE LOADS, PROPELLERS, ICE NAVIGATION. ICE FLOES, ICE CONDITIONS, ICE SOLID IN-TERFACE, VELOCITY, ICE DENSITY, FRIC-TION, TESTS.

TION, TESTS.

Results of a laboratory study on sce-propeller interaction conducted with a model sechecaker are presented. The tests were made in sec-free water, precut channels with regularly shaped see flores of different sizes, and breat-filled ex channels. The test results showed that the propeller torque and its standard desistion increased with both see flore size and ship speed. The dominant frequency in the torque fluctuations was found to be either the propeller speed or the ratio of stap speed to flore width. The effect of tee ingestion on propeller thinst could not be determined because of malfunction of the thinst component of the peopeller Jayamometer. The results suggest that difference in see density and in sechull fraction coefficiarin between model tosts and full scale tituls may be at least partially responsible for the lack of agreement between reque and powering requirements predicted from model propusion test results and those measured during full-scale tituls.

CONFIDENCE IN HEAT FLUX TRANSDUCER MEASUREMENTS OF BUILDINGS.

Flanders, S.N., 1985, 91(1), p.515-531, 12 refs

42-1375 HEAT TRANSFER, BUILDINGS, HEAT FLUX. TEMPERATURE MEASUREMENT, MEASUR-ING INSTRUMENTS.

ING INSTRUMENTS.

Confidence in the validity of heat flux transducer (HFT) measurements is sufficiently high that ASTM is preparing a standard practice for the use of HFTs on buildings. A key issue the standard practice will address it how to adjust the calibration of the HFT to the thermal environment of the measurement. Confidence in the use of HFTs is based in part on a propaga in of error analysis of key thermal influences on the accuracy of measurement. The user can expect the HFT to render a standard deviation of 10% of the heat flux measured. Field measurements confirm this expectation. However, the variety of heat flux mechanisms inherent in building construction requires continum this expectation. However, the variety of first mechanisms inherent in building construction requires that the investigator choose the measuring situation carefully. Convection, even in "fully insulated" spaces, can cause unexpected lateral heat flux and results that are difficult to interpret. More werk should be done with HFTs to investigate convection in walls and attics, as well as to investigate either lateral heat thus transfer mechanisms. other lateral heat flux transfer mechanisms

MP 2303 EVOLUTION OF FRAZIL ICE IN RIVERS AND

Daly, S.F., International Symposium on Cold Regions Heat Transfer, Edmonton, Alta., June 4-6, 1987. Proceedings. Edited by K.C. Cheng, V.J. Lunardinand N. Seki, New York, American Society of Mechanical Engineers, 1987, p.11-16, 35 refs.

42-1690 FRAZIL ICE, ICE CONTROL, TURBULENT FLOW, ICE FORMATION, STREAMS, FREEZE-UP, HEAT TRANSFER, ICE CRYSTALS, RIVER ICE, ICE PHYSICS, ICE MECHANICS.

ICE, ICE PHYSICS, ICE MECHANICS.

This paper presents a selective overview of the research into frazil ice. The development of theory, instrumentation, and control structures has not proceeded on parallel course for all stages of frazil evolution. The earliest, dynamic stage of frazil formation is probably the best described, yet there has as yet been no application of this theory to a practical situation. A fundamental understanding of frazil formation could lead to means of disrupting the formation, such as by artificial seedings, modification of the fluid turbulence, etc. The development of instrumentation, has increased our ability to view and sample frazil, but as yet has not provided much benefit for the design and siting of ice control structures. To date, the successful use of ice control structures. Theory or instrumentation has not made their job cavier, but the potential is large. A major task now is the synthesis of existing theory and instrumentation for application in ice control

EMATICS).

One of the most difficult and yet most interesting areas of heat transfer is conduction (or convection) with freezing or thawing. The inherent non-linearity of the problem along with the unknown moving interface precludes exact solutions for most practical cases. This has purred great effort to devise approximate solution methods which are accurate and of general application. Many of the known exact solutions are listed here along with a brief discussion of two approximate methods; the quasi-static and the heat balance integral. Space limitations rule out the inclusions of such useful variational methods as that of Biot or of a treatment in more detail.

FREEZEUP, FRAZIL ICE, ICE SOLID INTER-FACE, ICE ADHESION, HEAT TRANSFER, ICE FORMATION, MATHEMATICAL MODELS, DRAINAGE.

FORMATION, MATHEMATICAL MODELS, DRAINAGE.

The freezeup of trash racks by frazil ice occurs in a sequence that has not been quantitatively described. Because of the difficulty in observation and measurement, very little is quantitatively known about the concentration of frazil ice at the intake, the mechanism(s) of underwater ice adhesion, the deposition efficiency of frazil ice, the contribution of different heat transfer modes to the ice growth on the rack, and the relationship of the head loss through the rack to the flow velocity as a function of the mass of ice present. A comparison of the ice generation by conduction and convection with the mass of ice deposited on the rack from the flow indicates that deposition is the most significant mode of ice formation on the rack. Based on this, and other assumptions, a first generation mathematical model that describes the head loss through a trash rack during freezeup is developed. The mathematical model is developed for the case of a trash rack through which a constant discharge is maintained. The model is applied to laboratory data with good results

were obtained by modelling a section of a trash rack in a flume located in a cold room. Frazil ice produced in the flume caused the rack to freeze up while a constant discharge was maintained. The mathematical model can be used to suggest means, both structural and operational, of extending the time until total freezeup of a trash rack coccurs. Improvements in the mathematical model are suggested. occurs gested.

STRAIN-RATE AND GRAIN-SIZE EFFECTS IN ICE.

Cole, D.M., 1987, 33(115), p.274-280, 22 refs. 42-1822

ICE DEFORMATION, ICE CRYSTAL STRUCTURE, STRAINS, GRAIN SIZE, TESTS, STRESS STRAIN DIAGRAMS.

This paper presents and discusses the results of constant deformation-rate tests on laboratory-prepared polyerystalline icc. Strain-rates ranged from 0.000,000,1 to 0.1/s, grain-size ranged from 1.5 to 5.8 mm, and the test temperature was -5 C. At strain-rates between 0.000,000,1 and 0.001/s, the stress-strain-rate relationship followed a power law with an exponent of n=4.3 calculated without regard to grain-size. However, a reversal in the grain-size effect was observed below a transition point near 0.000,004/s the peak stress increased grain-size, while above the transition point he peak stress decreased with increasing grain-size. This latter trend persisted to the highest strain-rates observed. At strain-rates above 0.001/s the peak stress became independent of strain-rate. The unusual trends exhibited at the lower strain-rates are attributed to the influence of the grain-size on the balance of the operative deformation mechanisms Dynamic recrystallization appears to intervene in the case of the finer-grained material and serves to lower the peak stress. At comparable strain-rates, however, the large-grained material still experiences internal micro-fracturing, and thin sections reveal extensive deformation in the grain-boundary regions that is quite unlike the appearance of the strain-rate of the s This paper presents and discusses the results of constant boundary regions that is quite unlike the appearance of the strain-induced boundary migration characteristic of the fine-grained material MP 2312

AIRBORNE RIVER-ICE THICKNESS PROFILING WITH HELICOPTER-BORNE UHF SHORT-PULSE RADAR.

Arcone, S.A., et al, 1987, 33(115), p.330-340, 14 refs.

RIVER ICE, ICE COVER THICKNESS, SCATTER-ING, REMOTE SENSING, PROFILES, EQUIP-MENT, LAKE ICE, SURFACE ROUGHNESS,

The ice-thickness profiling performance of a helicopter-mounted short-pulse radar operating at approximate center frequencies of 600 and 900 MHz was assessed. The antenna packages were mounted 1.2 m off the skid of a small helicopter cies of 800 and 900 Mr12 was assessed. In the antenna packages were mounted 1.2 m off the skid of a small helicopter whose speed and altitude were varied from about 1.8 to 9 m/s and 3 to 12 m. Clutter from the helicopter offered minimal interference with the ice data. Data were acquired in Alaska over lakes (as a proving exercise) and two rivers, whose conditions varied from open water to over 15 m of solid ice with numerous frazil-ice formations. The most readily interpretable data were acquired when the ice or snow surface was smooth. Detailed surface investigations on the Tanana River revealed good correlations of echo delay with solid ice depth, but an insensitivity to frazilice depth due to its high water content. On the Yukon River, coinciding temporally coherent surface and bottom reflections were associated with solid ice and smooth surfaces All cases of incoherent surface returns (scatter) occurred over ice rubble. Rough-surface scattering was always followed by the appearance of bottom scattering but, in many cases, including a hanging-wall formation of solid frazil ice, bottom scattering occurred beneath coherent, smooth-surface reflections. Areas of incoherent bottom scattering investicontrol scattering occurred beneath conerent, smooth-surface reflections. Areas of incoherent bottom scattering investi-gated by drilling revealed highly variable ice conditions, including frazil ice. The minimum ice thickness that could be resolved from the raw data was about 0.2 m with the 600 MHz antenna and less than 0.15 in with the 900 MHz

ICE COVER THICKNESS, SEA ICE, ICE FLOES, PHOTOGRAPHY.

PHOTOGRAPHY.

The entire width of the antarctic sea ice zone was traversed in the vicinity of 0 deg longitude from July 18 to Sep 10, 1986. Ice thicknesses were measured by direct drilling, by helicopter profiling using an Exstar 100-MHz impulse radar system and by aerial photography. The results of the point measurements (drilling) are reported in this paper together with an indication of how the radar and photography data will be used to extend them so as to yield area-averaged ice thickness distributions. The main ice type across the entire width of the ice cover was consolidated pancake ice occurring in vast floes, this formed out of a 250-km-wide band at the advancing ice edge which comprised a concentrated field of individual pancakes in a matrix of razil ice. Preferred thicknesses of undeformed floes were 40-60 cm of ice covered with 5-15 cm of snow. The individual pancakes attained almost all of this thickness before consolidation, subsequent congelation growth was slow, estimated at 0.4 cm/d. The floes contained much small-scale roughness on the upper and lower surfaces due to rafting of pancakes at the time of consolidation, but pressure ridging was modest except in the far south. A few very thick (8-11 m) multiyear floes were observed embedded ridging was modest except in the far south thick (8-11 m) multiyear floes were observed in the pack at latitudes beyond 66S (Aut

DEFORMATION

This is a review of work on bending and buckling failure of floating ice sheets, along with the forces generated during ice/structure interaction

The focus is on the work published after 1980. Estimation of ice forces as a result of bending and buckling failure of an ice sheet can be made with a fair degree of confidence when the ice, structure interaction leads to one of the two modes of failure. The problem of multimodal failure of floating ice sheets needs further study.

HISTORY OF SNOW-COVER RESEARCH. Colbeck, S.C., 1987, Special issue, p.60-65, 31 refs. 42-1959

COVER, SNOW HYDROLOGY, AVA-SNOW LANCHES, HISTORY.

LANCHES, HISTORY.

The history of snow-cover research is divided into 4 distinct periods. Before 1900 there were systematic observations of snow but the tools were just being developed to begin serious research. From 1900 to 1936, many investigations were made because of the practical considerations of snow hydrology and snow avalanches Individuals began the assessment of snow water equivalent for forecasting run-off and the observation of snow structure and texture. Quantitative and physical investigations quickened after government-sponsored laboratories were established in 1936, the same year as the founding of the International Glaciological Society From 1936 through the 1960s, many detailed investigations were made into snow's physical properties and behavior Professional societies organized national and regional meetings, and published the results of snow research Many more laborationes became involved as knowledge about snow was developed and applied to run-off forecasting and avalanche defense Snow research surged again during the 1970s with the establishment of a new generation of snow scientists using more advanced theory, computers, and instrumentation As demands continue for solutions to snow problems with new emphasis on old themes, snow instrumentation As demands continue for solutions to snow problems with new emphasis on old themes, snow research generates knowledge about snow for a wide variety of applications

LOADS, GRAIN SIZE, ICE CRACKS.

The four-point-bend loading configuration is used here to study the flexural strength and fracture toughness of macrocrystalline SI type freshwater ice. The emphasis in this investigation was to minimize testing errors, prepare geometrically similar specimens milled to good accuracy, and to use a mechanical and repeatable method of notch formation. The question under study is Would a wide scatter in flexural strengths and fracture toughness results still occur in SI see of the inaccuracies in specimen preparation and variations. strengths and tracture toughness results still occur in Si nee if the inaccuracies in specimen preparation and variations in notch acuity were minimized, and if the specimen size were increased significantly? The basic tenet then is that any scatter would be predominantly due to crystal orientation effects, grain size effects, variations in the predominant c-axis orientations, as well as both specimen size and specimen geometry.

A new type of refrigerated model ice was tested for flexural A new type of refrigerated model ice was tested for flexural strength and elasticity in a small basin. This model coc, termed "EG, AD/S" ice by the developer, Timeo of NRCC, is produced by freezing a solution of three chemicals ethylene glycol, aliphatic detergent, and sucrose. A small-scale laboratory investigation was conducted to determine some of the mechanical properties of the EG, AD/S ice and to make modifications to the chemical formula as needed. The results of these extra were found to compare well were and to make moniteations to the centineal formula as necessor. The results of these tests were found to compare well with Timco's results for EG.AD.S i.e. as well as with tests on urea i.e. grewn in the same tank. Described are some of the problems with this new ice, including excessive sudsing

and bacterial blooms, and the techniques used to try to alleviate them Also discussed are several unique aspects of dealing with ice sheet growth and mechanical properties testing in a small tank.

HEAT TRANSFER PERFORMANCE OF COM-MERCIAL THERMOSYPHONS WITH IN-CLINED EVAPORATOR SECTIONS.

TY, TESTS, EVAPORATION, EQUIPMENT.
Laboratory tests have been conducted with two full-size, two-phase commercial thermosyphons in an atmospheric wind tunnel at the U.S. Army CRREL. The test variables were wind speed and evaporator inclination angle. The air speed ranged from 0 to 5.2 m/s. The evaporator angles were varied from 0 to 12 deg measured from the horizontal. The effect of nearby walls on thermosyphon performance was also investigated. Tests were conducted with walls oriented parallel, at 45 deg and at right angles to the air flow direction. The air temperature for all tests was about -18 C. Test results are presented with thermal conductance of the thermosyphon as a function of wind speed and evaporator inclination angle. The heat transfer conductance was found to increase with increasing wind speed and increasing evaporator inclination angle.

LOW TEMPERATURE TESTS, HEAT TRANS-FER, WIND VELOCITY, TEMPERATURE EF-FECTS, EQUIPMENT, WATER FLOW, ICE GROWTH, MEASURING INSTRUMENTS.

GROWTH, MEASURING INSTRUMENTS.

The exposure of portable electronic data logging equipment to extreme low temperatures usually leads to system failure. To overcome this difficulty at northern remote sites, the use of a thermosyphon to transfer energy stored in the ground to an insulated instrument shelter was tested. The results of the test showed that the thermosyphon maintained the instrument shelter well above the outdoor ambient air temperature during cold spells. Laboratory tests were conducted with two-phase full-size thermosyphons to freeze water in a test basin. The test variables were wind speed and in a test basin The test variables were wind speed and water velocity A single-phase thermosyphon was also tested for growing ice. The heat transfer conductances of the thermosyphons were estimated for various wind speeds. in a test basin of the thermosyphons were estimated for various wind speeds. The use of thermosyphons placed in rivers has been proposed to collect transported frazil ice to augment ice dam formation or prevent frazil ice from interacting with downstream hydraulic structures. Laboratory tests were conducted with model two-phase thermosyphons in a refrigerated flume to test this concept. Frazil ice was generated upstream of a thermosyphon array placed across the flume perpendicular to the flow. The ability to collect frazil was determined by measuring the head loss across the array with time. Comparisons were made with an array of solid aluminum rods with the same dimension as the model thermosyphons. The influence of wind was also investigated

ON THE DETERMINATION OF THE AVERAGE YOUNG'S MODULUS FOR A FLOATING ICE COVER

Kerr. A.D., et al, Feb. 1988, 15(1), p.39-43, 11 refs. Haynes, F.D.

FLOATING ICE, LOADS (FORCES), ICE ELAS-TICITY, ANALYSIS (MATHEMATICS), PRES-SURE

SURE.

First, the meaning of Young's modulus for a floating ice cover is discussed. A method often used for determining the average modulus of the cover, E(av), consisting of loading an ice cover vertically with a rigid disc, is then presented and a possible shortcoming of the calculation method used is pointed out. It is related to the fact that the contact pressure distribution between disc and ice cover is generally not known. To clarify this issue, a comparative study was conducted to establish the effect of related pressure distributions on the calculated E(av)-value. It was found that the limiting cases—like the uniformly distributed pressure and the uniform line distribution along the disc boundary—yield E(av) that are close to each other. Also, for the range of parameters under consideration, the E(av) obtained using the solution for a concentrated force is close. The using the solution for a concentrated force is close. The paper concludes by showing how the generated graphs may be used to simplify the calculation of E(av) for an ice

ICE CRACKS, ICE CRYSTAL STRUCTURE, GRAIN SIZE, CRACK PROPAGATION, ANISO-TROPY, TESTS, MODELS.

TROPY, TESTS, MODELS.

This paper examines in detail two likely mechanisms of microcrack formation in polycrystalline ice and pays special attention to the grain size dependencies of each mechanism Under consideration are the Zener-Stroh dislocation pileup mechanism and an elastic mechanism based on the anisotropy of the ice lattice. Calculations for the pileup mechanism indicate that although the dislocation velocity is relatively low, a critical-sized pileup can form under plausible test conditions. Quantification of the elastic anisotropy mechanism indicates that it operates over approximately the same stress levels as the pileup mechanism and exhibits the same grain size dependency. The results of observations on grain size dependency. The results of observations on the microcracking of laboratory-prepared freshwater ice having randomly oriented equiaxed grains are used to test the model predictions. The work gives detailed descriptions of the methods used to quantify each model

THERMAL INSULATION, BUILDINGS, HEAT TRANSFER, MILITARY FACILITIES, CONVECTION, HEAT FLUX, ACCURACY, ECONOMIC ANALYSIS, THERMAL CONDUCTIVITY

ANALYSIS, THERMAL CONDUCTIVITY
As-built drawings and handbook calculations of R values are often inadequate bases for investment decisions regarding improved insulation of U.S. Army buildings. Reported field and laboratory experience indicates that a technique employing surface-mounted heat flux sensors (HFSs) in conjunction with infrared thermography (IRT) can yield reliable estimates of R values. This technique employs IRT to position HFSs and thermocouples at representative locations on walls and roofs or attus to sequent heat flow and temperature data for estimating R values. This paper reports on the application of this technique at Ft. Carson, Colorado, and Ft. Richardson, Alaska, to 8 family housing units, a temporary office building, and a barracks. Infrared thermography of these buildings detected few thermal anomalies, but measurement of several walls with HFSs and thermocouples (typically at 6 locations spaced vertically on each wall) revealed significant variation in estimated R values, this variation is attributable to convection, even within fully insulated walls.

is significant for proper placement of sensors and indicates that installed fibrous insulation can lack the ability to quell convection. The insulating ability of walls containing poorly installed mineral fiber batt insulation was much worse than would be indicated by the design handbook values. Somattic insulation performed exactly as expected; some was at least 40% worse than expected.

SHAPE OF CREEP CURVES IN FROZEN SOILS AND POLYCRYSTALLINE ICE.

Fish, A.M., Nov. 1987, 24(4), p.623-629, 12 refs.

SOIL CREEP, ICE CREEP, FROZEN GROUND MECHANICS, ICE MECHANICS, RHEOLOGY, MATHEMATICAL MODELS, STRESSES, TEM-PERATURE EFFECTS.

A new method was developed for determining creep parameters, particularly the time to failure, from a single linear plot in which an individual creep curve forms a straight line for primary and tertiary creep. Secondary creep is considered to be a principal point on this line that predetermines the onset of failure. The times to failure can be predicted, even when creep tests are not complete, by extrapolating information obtained for primary creep. Based upon T.H. Jacka's test data, prediction of creep strain was evaluated using the constitutive equation of A.M. Fish for entire creep and compared with the modified Sinha equation of M.F. Ashby and P. Duval for attenuating creep as well as with models for primary and secondary creep. It is shown that the shape of the creep purves, and thus the creep parameters, varies with stress, temperature, and other factors. Hence, a family of creep curves cannot be described by a constitutive equation with a single set of creep parameters that do not take into account these variations without loss in the accuracy of the creep strain calculations. MP 2330 A new method was developed for determining creep parame-

BOREHOLES SURFACE MIGRATION. REMOTE SENSING, ICE MECHANICS, VELOCI-TY, TOPOGRAPHIC FEATURES, DRILLING, GREENLAND—CAMP CENTURY.

OREENLAND—CANIT CENTORI.

Directional surveys of the bore-hole at Camp Century, Greenland were made in 1966, 1967 and 1969. From these sirveys a surface velocity of \$5 myr in the direction 10 deg was computed. The position of the 60 m meteorological tower near the bore-hole was measured in 1977 and 1986 with satellite navigation equipment. These measurelogical tower near the bore-hole was measured in 1977 and 1986 with satellite navigation equipment. These measurements show a surface velocity of 3.5 m/yr in the direction 235 deg. Measurement of the surface topography in 1986 shows the bore-hole is situated on a local sloping ite divide. A differential magnetometer was used to locate the drill tower. Hand augering verified the location and showed the drill tower was buried 6.5 to 7 m beneath the 1986 snow surface, as expected from the depth-age relation. The casing was not identified. Extension of the easing to the snow surface and resurvey of the bore-hole will provide urgently needed information on the variation of ice flow urgently needed information on the variation of ice flow urgently needed information on the variation of ice flow with depth

ICE COVER THICKNESS, SUBGLACIAL OBSER-VATIONS, ELECTROMAGNETIC PROSPECT-ING, AIRBORNE RADAR, SNOW COVER THICKNESS, ICE CONDITIONS, SOUNDING, SEA ICE, PROFILES, UNITED STATES—ALAS-KA PRUDHOE BAY

A study was made in May 1985 to determine the feasibility of using an arborne electromagnetic sounding system for profiling sea ice thickness and the sub-ice water depth and conductivity. The study was made in the area of Prudhoe

Bay, Alaska Bay, Alaska The multifrequency airborne electromagnetic sounding system consisted of control and recording electronics sounding system consisted of control and recording electronics and an antenna. The electronics module was installed in a helicopter, and the 7 m long tubular antenna was towed beneath the helicopter at about 35 m above the ice surface. For this electromagnetic system, both first-year and second-year sea ice could be profiled, but the resolution of ice thickness decreased as the ice became rough. This decrease was associated with the large footprint of the system, which effectively smoothed out the sea ice relief Under-ice water depth was determined, as was seawater conductivity. The results of the feasibility study were encouraging, and further system development is therefore warranted.

ONSHORE ICE PILE-UP AND RIDE-UP: OB-SERVATIONS AND THEORETICAL ASSESS-MENT.

Kovacs, A, et al, Arctic coastal processes and slope protection design Edited by AT Chen and CB Lei-dersdorf, New York, American Society of Civil Engineers, 1983, p.108-142, Refs. p.138-142. Sodhi, D.S.

FAST ICE, ICE PILEUP, ICE OVERRIDE, ICE LOADS, OCEAN CURRENTS, WIND FACTORS, SEASONAL VARIATIONS, ICE SHEETS, PRES-SURE RIDGES.

An overview of shore ice pile-up and ride-up observations is presented and the forces associated with ice rubble formation are discussed. Historical and recent observations indicate that the onshore movement of ice is generally a spring or fall event associated with wind and/or water driving forces. The occurrence of this phenomenon is relatively unpredictable and has resulted in the destruction of structures and loss of life. The analytical and experimental works. and loss of life The analytical and experimental work undertaken to date tends to show that low driving forces per unit width can cause shore ice pile-up or ride-up, but that high concentrated forces can occur during such events and loss of life along local areas of resistance. An analysis of the ice sheet failure process is given which indicates that the average ice rubble building force per unit width is a function of rubble height, to a power between 1 and 2, depending on the total ice sheet width undergoing failure

42-334 METAL SNOW FRICTION, WATER FILMS, SNOW COVER, SNOW MELTING, GRAIN SIZE, TEMPERATURE EFFECTS, VELOCITY, SHEAR STRENGTH, FRICTION, ANALYSIS (MATH-

EMATICS).

Three components of the kinetic friction of snow are described but only the lubricated component of friction is treated in detail. This component depends upon the thickness of water films which support a slider on snow grains over a small fraction of its area. The thickness of the film decreases with ambient temperature in a manner which is sensitive to the thermal conductivity of the slider. The minimum value of friction at any temperature is reached at an intermediate value of speed because friction decreases as the slider first begins to move and the films form but then increases at higher speeds because of the shear resistance At sub-freezing temperatures a small area in the front part of the slider is dry and the friction is high. Once the water film is formed it increases in thickness towards an equilibrium value which can be very sensitive to slider properties, speed, and temperature. It appears that the mechanisms may be very different for hydrophobic and hydrophilic sliders. From the equations derived here it is clear why friction decreases with repeated passes over the same snow.

TION.
"Impulse" radar and ice property data were obtained on a second-year sea ice floe. These data were used to develop a relationship for estimating the ice thickness from just the two-way time-of-flight of the impulse radar electromagnetic wavelet traveling from the surface to the ice "bottom" and back to the surface. The relationship developed allows estimation of the thickness of sea ice from about 1 to 8 m, with or without a snow cover. The data revealed that the apparent dielectric constant of sea ice decreased with increasing ice thickness until the thickness reached about 4 m. For sea ice thickness that the apparent dielectric constant became relatively constant. With the use of a model for determining the electromagnetic prop.rit.s. of sea ice from its physical properties, as determined from ice cores, the electromagnetic properties were calculated sersis depth. The model results were then compared with the electromagnetic properties determined from field measurements. The two results were in good agreement.

The Polar Ice Prediction System (PIPS) is an ice forecasting model run on a daily basis at the U.S. Navy's Fleet Numerical Oceanographic Center (FNOC). The model was originally developed by Hibler (1979) and subsequently modified by Preller (1985) to run on FNOC'S Cyber 205. Atmospheric forcing fields are derived from the Naval Operational Global Atmospheric Prediction System (NGGAPS). PIPS is run on a 127-km resolution 47 x 25 grid, which covers the entire Arctic Basin and substantial parts of the Greenland and Norwegian Seas. The system produces forecasts of ice drift, thickness, concentration and divergence at 24-hr intervals out to 144 hr (6 days). Although PIPS is run on a daily basis, the concentration field is initialized weekly using a digitized version of the concentration analysis field prepared by the Naval Polar Oceanography Center at Sutland, Maryland. The system's ability to forecast tee drift, concentration and ice edge location was assessed for the period, prepared by the Naval Polar Oceanography Center at Sutland, Maryland
The system's ability to forecast use drift, concentration and ice edge location was assessed for the period, from June 15 to October 15, 1986. The PIPS drift predictions were generally excessive, although the predicted drift directions were reasonable Mean concentration differences between the PIPS forecasts and the analyses were about 12%
Although ice edge location was reasonably predicted in most cases, the model demonstrated a trend of rapid in most cuses, the model demonstrated a trend of rapid ice retreat in the Chukchi and East Siberian Seas that was unrealistic.

MP 2348 EXPERIMENTAL DETERMINATION OF THE FRACTURE TOUGHNESS OF UREA MODEL

THICKNESS, FLEXURAL STRENGTH.
The use of different types of model ice in examining ice/structure interactions requires a better understanding of the fracture behavior of these materials in order to accurately interpret the results of model tests. There have been only a limited number of fracture tests performed on model ice. A preliminary experimental study of the fracture toughness of the urea-doped model ice used in the test basin at CRREL lass been completed. An "in-situ" wedge-loaded TDCB (tapered double-cantilever beam) specimen geometry was chosen. An expression for the fracture toughness as a function of applied load, specimen geometry, and ice thickness was developed using a finite element program.

ICE LOADS, OFFSHORE STRUCTURES, STRESSES, ICE CRACKS, EXPERIMENTATION, MEASURING INSTRUMENTS, ACCURACY, ICE SHEETS

Experiments were conducted to determine the accuracy of calculating ice loads on offshore structures using ice stress measurements and a surface integral method. Biaxially-sensitive stress sensors were installed near an ice sheet edge and a flat plate instrumented indentor was pushed against the ice edge to simulate a distributed load on the boundary of a semi-infinite plate. Two experiments were conducted. The first determined the agreement between stress measurements and calculated results for the corresponding analytic solution and examined the accuracy of the surface integral method. The second examined the influence of cracks in the ice sheet on the accuracy of the surface integral method. The measured ice stresses were of the same order but less than the calculated using theory. The calculated indentor loads using the plane surface integration were within 8 to 30% of th: measured loads. Calculated loads using a cylindrical integration surface were only within 40 to 50% of the measured loads due to stress sensor resolution limitations. The surface integral method is a viable way to calculate structural ice loads using in-situ stress measure-Experiments were conducted to determine the accuracy of limitations. The surface integral method is a viable way to calculate structural ice loads using in-situ stress measurements. Accuracy of the load calculations is limited by the fidelity of representing the stress along the surface of the integration using widely-spaced stress measurements

FROZEN GROUND PHYSICS, OIL STRUCTURE, MICROSTRUCTURE, SCALLYING ELECTRON MICROSCOPY, X RAY ANALYSIS, CLAY, POROSITY, ICE SUBLIMATION, CHEMICAL ANALYSIS, GRAIN SIZE.

ANALYSIS, GRAIN SIZE.
Physical properties of bentonite, dickite and sand samples for freezing experiments were examined with a scanning electron microscope (SEM), and elemental compositions were measured with an energy dispersive x-ray (EDX) analyzer. Bentonite from Umiat, Alaska, is a typical cold-regions swelling clay with thin, crumpled and folded structures. The soil samples with relatively high water contents were frozen, and the frozen characteristics were examined with the SEM equipped with a cold stage. SEM images of frozen bentonite and dickite showed characteristics segregated re and coagulated soil patterns formed during freezing processes and porous structures formed during the sublimation stage of ice in frozen soils. However, frozen sand showed no typical ice segregation and sand grain coagulation because of the large grain size. The freeze sublimation process of frozen clay and silt increases the permeability to water vapor because of the porous structure formation.

ANALYSIS (MATHEMATICS).

A new experimental method is introduced to determine the rate of water movement caused by temperature gradients in unsaturated frozen soils. When a linear temperature distribution is imposed on a closed soil column with initially a uniforin water content, a redistribution of water occurs in the co. unm. As time increases, the profile of water is stabilized to appreach a stationary profile, which is used to calculate the rate of water movement due to temperature gradient. The theoretical justification of the method is presented and the feasibility of the method is demonstrated by experiments with a matine-deposited clay.

UNFROZEN WATER CONTENT, SOIL WATER, FROZEN GROUND, TEMPERATURE EFFECTS, DIELECTRIC PROPERTIES, EXPERIMENTATION. NUCLEAR MAGNETIC RESONANCE, REFLECTIVITY, WATER CONTENT.

REFLECTIVITY, WATER CONTENT.

A laboratory testing program was carried out to compare two independent methods for determining the unfrozen water content of soils. With the TDR method, the unfrozen water content is inferred from a calibration curve of apparent inelectric constant versus volumetric water content, determined by experiment. Previously, precise calibration of the TDR technique was hindered by the lack of a reference comparison method, which NMR now offers. This has provided a much greater scope for calibration, including a wide range of soil types and temperature (unfrozen water content). The results of the testing program yielded a relationship between that is largely unaffected by soil type, although a subtle but apparent dependency on the texture of the soil was noted. It is suggested that this effect originates from the lower valued dielectric constant for adsorbed soil water. In spite of this, the general equation was cented may be considered adequate for most practical program of the standard error estimate is 0.015 cu cm/cu cm, ai, hough, if desirable, this may be reduced by calibrating for individual soils. But guidelines on system and probe design are offered to help ensure that use of the TDR method will give results consistent with the relationship presented. with the relationship presented

BOREHOLE INVESTIGATIONS OF THE ELEC-TRICAL PROPERTIES OF FROZEN SILT.

Arcone, S.A., et al, International Conference on Permafrost, 5th, Trondheim, Norway, Aug. 2-5, 1988. Proceedings, Vol.2. Edited by K. Senneset, Trondheim, Norway, Tapir Publishers, [1988], p.910-915, 16 refs.

PROPERTIES, BOREHOLES, GROUND ICE,
FROZEN GROUND TEMPERATURE, DIELECTRIC PROPERTIES, ATTENUATION, SEDI-MENTS, WATER CONTENT.

MEN'IS, WATER CONTENT:
The dielectric constant and attenuation rate of short radiowave pulses in frozen Fairbanks silt have been measured between boreholes 12 m deep and spaced between 4.4 and 176 m. The ranges for volumetric ice content and temperature were 44 to 79% and -60 (surface, early Apr.) to -0.7 C (bottom) respectively.

The pulses lasted approximately 30 ns, had a power spectrum centered near 100 MHz, and were transmitted and received at the same depth Diesertic constants were determined from the propagation. and were transmitted and received at the same depth Dielectric constants were determined from the propagation time
delay of the the leading edge and there was no significant
dispersion. Attenuation rates (dB/m) were determined
by comparing signal levels received between different borehole
pairs and were adjusted for geometric spreading losses Concurrent borehole de resistivity measurements allowed estimates
of the separate contributions of various loss mechanisms
The results show the dielectric constant to vary between
4.3 and 7.0 and to correlate well with the volumetric ice
content, but not with temperature. Average attenuation
rates at any particular depth varied between 14 and 40
dB/m. The lowest values occurred in the sections with
the higher ice content. No more than 08 dB/m could
be ascribed to conductive absorption losses, suggesting that
scattering is an important loss mechanism

SEASONAL VARIATIONS IN RESISTIVITY AND TEMPERATURE IN DISCONTINUOUS PERMAFROST.

Delaney, A.J., et al, International Conference on Permafrost, 5th, Trondheim, Norway, Aug. 2-5, 1988. Proceedings, Vol.2. Edited by K. Senneset, Trondheim, Norway, Tapir Publishers, (1988), p.927-932, 16 refs.

WATER CONTENT, GRAIN SIZE, FROZEN
GROUND TEMPERATURE.

Electrical resistivity and temperature were measured in two 12.2-m-deep boreholes in interior Alaska in perennially frozen ice-rich sit and in coarse-grained alhvium. Seasonal temperature and resistivity changes were most noticeable in the upper 6 m at both sites, with resistivity varying more than several thousand ohm-m during, no year. Resistivity profiles were compared with lithology, temperature and moisture content. At the alluvium site reristivity and grain size strongly correlated. Values ranging over 10,000 ohmmoccurred with coarse-grained material and values an order of magnitude lower occurred in the fine-grained material section. At the ice-rich site site, resistivity values were generally lower, but in agreement with values for the fine-grained part of the alluvial section. Lithologic variations in the discontinuous permafrost zone can be as important as the high permafrost temperatures and correspondingly large unfrozen water contents in accounting for significant seasonal resistivity changes in fine-grained sediment. Electrical resistivity and temperature were measured in two

PRUDHOE BAY.

Electrical resistivity measurements, at three sites in Prudhoe Bay, Alaska, were made to provide an understanding of manne modification to coastal permafrost, and to evaluate D.C. resistivity techniques for coastal subsea permafrost studies. The measurements were made using Wenner electrical resistivity soundings. Profiles extended 2.8 km offshore and inland beyond the last signs of tundra modification by coastal processes of tundra modification with a floating cable, and inland measurements were made using driven electro-les. The observations indicate that

the electrical properties of permafrost beneath the coastal bluff and adjacent tundra are rapidly modified by coastal erosion and periodic flooding during storms. Along one control line, apparent resistivity changes corresponded with the configuration of the top of ice-bonded permafrost observed by Baker (1987). Modeling supported by the control data permitted a close interpretation of the position of the top of ice-bounded subsea permafrost and provided a range of real resistivities for offshore materials.

FROST HEAVE FORCES ON H AND PIPE FOUNDATION PILES.

Buska, J.S., et al, International Conference on Perma frost, 5th, Trondheim, Norway, Aug. 2-5, 1988. Proceedings, Vol.2. Edited by K. Senneset, Trondheim, Norway, Tapir Publishers, [1988], p.1039-1044, 6

FAIRBANKS.

The magnitude and variation of forces and shear stresses, caused by frost heaving in Fairbanks silt and the adfreeze effects of a surface ice layer and a gravel layer, were determined as a function of depth along the upper 275 m of a pipe pile and an H pile for three consecutive winter seasons (1982-1985)

The peak frost heaving forces on the H pile during each winter were 752, 790 and 802 kN

Peak frost heaving forces on the pipe pile of 1118 and 1115 kN were determined only for the second and third winter seasons.

Maximum average shear stresses acting on the pipe pile were 627 and 972 kPa for the second and third winter seasons.

The surfficial cell layer may have contributed pipe pite were 02/ and 9/2 kfa for the second and third winter seasons. The surfficial feel leyer may have contributed 15 to 20% of the peak forces measured on the piles. The gravel layer on the H pile contributed about 35% of the peak forces measured.

ING, TESTS, FREEZE THAW CYCLES, TEMPF R-ATURE CONTROL, EQUIPMENT.

A new freezing test for determining the frost susceptibility of soils used in pavement systems is designed to supplaint estandard CREEL freezing test. This new test cuts the time required to determine frost susceptibility in half it also allows for the determination of both the frost heave and thaw weakening susceptibilities and considers the effects of freeze-thaw cycling. The new freezing test also eliminates much of the variability in test results by completely automating the temperature control and the data observations.

TION. CAPILLARITY, POROSITY.

One potential use of geotextiles is horizontal placement in soil above the water table to act as a capillary break orbarrier to mitigate frost heave. A capillary break works because larger pore sizes and/or wetting angles of the material than surrounding soil result in 10 er unsaturated hydraule conductivity and lowered height of capillary rise of water. This reduces frost heave by limiting the rate of upward water migration. Fix series of open-system, unidirectional frost-heave tests were run in which 3 nonwoven polypropylene geotextiles were tested for their ability to mitigate frost heave. Certain fabries were successful in reducing frost heave by as much as 35%. Test results also indicate that the optimum fabric thickness required to mitigate frost high ce is a function of soil type as well as properties of the geotextile.

EFFECT OF VARIABLE THERMAL PROPERTIES ON FREEZING WITH AN UNFROZEN WATER CONTENT.

Lunardin, V.J., International Conference on Perma-frost, 5th, Trondheim, Norway, Aug. 2-5, 1988. Pro-ceedings, Vol.2. Edited by K. Senneset, Trondheim, Norway, Tapir Publishers, 1988₁, p.1127-1132, 17 refs.

TREEZING POINTS, THERMAL CONDUCTIVITY, UNFROZEN WATER CONTENT, HEAT TRANSFER, PERMAFROST THERMAL PROPERTIES, PHASE TRANSFORMATIONS, TEMPERATURE EFFECTS, GROUND THAWING, ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).
While many materials undergo phase change at a fixed temperature, the variation of unfrozen water with temperature causes a soil system to freeze or thaw over a finite temperature range. Exact and approximate solutions are given for conduction phase change of plane layers of soil with unfrozen water contents that vary linearly and quadratically with temperature. The temperatures and phase change depths are found to vary significantly from those predicted for the constant temperature (Neumann) problem. The thermal conductivity and specific heat of the soil within the mushy zone varied as a function of unfrozen water content. The effect of specific heat is negligible and the effect of variable thermal conductivity can be accounted for by a proper choice of thermal properties used in the constant thermal property solution.

Chamberlain, E.J. 42-4032

GROUND THAWING, SOIL WATER MIGPA-TION, FROZEN GROUND, WATER CONTENT, TESTS, ICE LENSES, FROST HEAVE, ICE FOR-

MATION.

Open and closed system tests on prefrozen silt and elay were conducted to investigate moisture migration in frozen soils during thawing. In all tests, an increase in water content just below the thawing front was observed. In some cases, a thawing fringe, ice lenses and frost heave were recorded. Water migration into the frozen part of thawing soil was greatly reduced after a continuous ice lens had formed across a sample. A regelation mechanism for ice formation in frozen soil during thawing is suggested.

STRUCTION MATERIALS, STRESSES.

Water level variations caused by wind, tides or seiche action during periods of open water seldom test the integrity of marine structures. Yet these same variations combined with an ice sheet may severely damage or completely destroy the same structures. Light-duty, pile-founded dock structures, typical of marinas, are especially susceptible to this type of environmental damage. As a wave passes under the ice sheet. Subsequently the piles are subjected to an uplifting force equivalent to the hydrostatic force associated with the ice sheet deflection. Over the course of a winter this repeated loading may incrementally extract the pile from its foundation. This laboratory study used a two-step approach for investigating the uplifting ice force phenomenon. First, a testing technique that reproduced the ice condition surrounding a prototype pile was developed in the second phase, the testing technique was used to evaluate methods of passively protecting the piles from induced uplift. Highlights of the tests are reported here, but a complete discussion of the tests are reported by Zabilansky (1987)

FRAZIL ICE, ICE FORMATION, ICE PHYSICS, ICE NAVIGATION, CHANNELS (WATER-WAYS), ICE JAMS, WATER FLOW, ICE STRENGTH, MEASURING INSTRUMENTS.

STRENGTH, MEASURING INSTRUMENTS.

With the increased utilization of flood plains, navigation and power generation in northern climates, it becomes increasingly important to understand the engineering characteristics of frazil ice accumulations. Frazil is generated and accumulates over large areas in waterways. Navigation through such great amounts of frazil will be impeded. Power generation suffers from the restricted flow caused by frazil accumulation. Having been generated in large quantities and attached as underhanging dams, frazil significantly increases flooding potentials through channel restrictions and an increase in the total ice volume in a waterway. Techniques for measuring the physical properties of frazil ice are presented. These data will assist in predicting the flow patterns and the jamming potential in a waterway, the properties include porosity, density, vane shear strength, permeability and a measure of the structural strength (expressed through plate load bearing, dilatometer, and penetrometer or rammsonde data). Further characteristics include remote sensing of the accumulation and flow profiling beneath the accumulations. Examples of the acquired data are given

—HUDSON RIVER.
Field studies of a reach of the Hudson River have focused on developing a technique to induce the controlled breakup of an ice cover or ice jam by releasing water from an upstream dam. A series of abrupt dam releases generated long-period river waves of different magnitudes, durations and spacings that caused changes in river stage, water surface slope, flow velocity, energy gradient of the flow, and integrity of the ice cover. We monitored river stage and ice cover response at several locations, and repeated the stage measurements with the same releases during open water conditions. These studies have revealed that pulsed releases of a practical magnitude were effective in removing the ice cover from the reach, and they provide basic data for more general analysis of river ice cover breakup.

RIVER ICE, ICE BREAKUP, HYDRODYNAMICS, ICE STRENGTH, MATHEMATICAL MODELS, THEORIES, DYNAMIC PROPERTIES, ICE

We have formulated a theory of dynamic ice breakup that is based on the data and observations presented in part 1 of this paper and additional observations of breakup on other rivers. The hydrodynamic forces that cause a dynamic breakup depend on the flow energy gradient, and resistance is a function of ice strength and ice cover support. In this paper we focus on the factors that affect the energy this paper we locus on the factors that affect the energy gradient, and we treat ice strength and breakup empirically Data that directly test the theory and quantify the relationship between river waves and ice breakup observed in the field were obtained by adapting a numerical model to the Hudson River study reach. The theory provides a basis for understanding the wide spectrum of observations of ice cover breakup and ice jam formation and release.

POLYMERS, CONSTRUCTION MATERIALS, DEGRADATION, FREEZE THAW CYCLES, TEMPERATURE EFFECTS, HUMIDITY.

TEMPERATURE EFFECTS, HUMIDITY.

This study focuses attention on low-temperature hygrothermal effects which influence the short- and long-term behavior and characterization of polymeric composite materials. A review of the literature reveals a searcity of low-temperature material performance data needed for design of composite materials for cold regions applications. Four problem areas are identified (1) hygrothermal residual stresses, (2) material degradation due to low-temperature environmental cycling; (3) moisture effects on freeze-thaw cycling; and (4) long-term synergistic effects of combined loading history and environmental exposure on material durability. A brief review of past work is presented and areas identified where more research is needed to develop the data base required for design of composite materials for cold environments.

WMO SOLID PRECIPITATION MEASURE-MENT INTERCOMPARISON AT SLEEPERS RIVER RESEARCH WATERSHED. Bates, R.E., et al, 1987, 44th, p.1-7, 6 refs. Pangburn, T., Greenan, H. 43-384

SNOWFALL, PRECIPITATION GAGES, MEA-SURING INSTRUMENTS, ACCURACY, WATER-SHEDS, SNOWSTORMS. SNOWFALL

The US Army Cold Regions Research and Engineering Laboratory is a member of the World Meteorological Organization (WMO) group tasked with evaluation of solid precipitation measurement procedures and instrumentation. The NOAA/CRREL Sleepers River Watershed in Danville, VT, was selected as the site for these tests in 1986, and precipitation was selected as the site for these tests in 1980, and precipitation gauges and sup-orting meteorological instrumentation were installed in the fall of 1986. This paper gives descriptions of the precipitation gauges evaluated and preliminary results obtained for a few snowstorms that occurred during the first winter of operation.

MP 2397 SOME OBSERVATIONS ON THE CHARACTER OF SNOW.

SNOWMELT. RUNOFF FORECASTING. TEMPERATURE, MELTWATER. STREAMS, MODELS.

STREAMS, MODELS.

For the 1986 snowmelt season at the W-3 subwatershed of the Steepers River Research Watershed, a technique was developed to quantify the volume and timing of snowmelt runoff using stream water temperature. A method reported by Kobayashi (1985) for separation of the snowmelt hydrograph was tested. A method employing air temperature and solar radiation was developed which was used to calibrate the SSARR model Improvements in the predictive capabilities of SSARR were attained using this method

ICE JAMS, CLIMATIC FACTORS, AIR TEMPER-ATURE, RIVER ICE, PRECIPITATION (METEOROLOGY), METEOROLOGICAL FACTORS, UNITED STATES—SOUTH DAKOTA— WHITE RIVER.

Weather records for stations in South Dakota for the winter months from 1921-1984 were examined to detect any long-term trends, and to determine possible relationships between climate and ice-jam occurrence on the White River. Analysis climate and ice-jam occurrence on the White River. Analysis of the observed average monthly winter air temperatures at Kennebec. South Dakota, revealed warmer Decembers and Januaries occurring between 1930 and 1950. Five of the seven ice-jam winters that were atuded in detail occurred after 1950, and during this period significantly lower temperatures were recorded in Jan. However, no consistent pattern between below-normal seasonal freezing temperatures, or above-normal precipitation amounts, and ice-jams was noted

MP 2400 STUDY OF DYNAMIC ICE BREAKUP ON THE CONNECTICUT RIVER NEAR WINDSOR, VER-MONT.

ICE BREAKUP, RIVER ICE, FLOODS, RIVER FLOW, ICE CONDITIONS, DAMAGE, BRIDGES, ICE CONTROL, STATISTICAL ANALYSIS, ICE JAMS, UNITED STATES—VERMONT—CON-NECTICUT RIVER.

JAMS, UNITED STATES—VERMONT—CONNECTICUT RIVER.

The Cornish-Windsor bridge is the longest covered bridge in the United States and has significant historical value At a large peak flow, dynamic ice breakup of the Connecticut River can threaten the bridge and cause flood damage in the town of Windsor, Vermont. Throughout the 1985-86 winter we regularly monitored ice conditions, including a midwinter dynamic ice breakup on 27 January, and conducted a series of controlled release tests over the operating range of the turbines at Wilder Dam upstream. These observations were analyzed in light of more than 60 years of temperature and discharge records. Our analysis indicates that river regulation, escents alternatives for ice management that would minimize the probability of bridge damage and flooding during breakup. The flow can be regulated early in the winter to promote the growth of a stable ice cover, minimizing the total ice production in the reach. In the weeks prior to breakup, sustained releases and above freezing air temperatures cause melting, weakening and gradual breakup of the ice, greatly reducing the flooding potential. Also it is possible to produce a controlled ice breakup at lower stage and discharge than now occurs during major natural events. All of these ice control alternatives have associated power production costs.

MP 2401 COMPARISON OF SNOWFALL AMOUNTS AND SNOW DEPTHS FOR LOCATIONS IN GERMANY AND THE NORTHEAST UNITED

Bates, R.E., et al, LOSAEL, TWI Conference, 8th, Las Cruces, New Mexico, Dec 1-3, 1987. Proceedings, Vol I, White Sands Missile Range, NM, U.S. Army Atmospheric Sciences Laboratory, May 1988. p 107-117. 9 rcfs.

A simulation scheme is developed that estimates salinity A simulation scheme is developed that estimates salinity profiles for first-year sea ice during the growth season as a function of the growth his ory of the ice. The model considers the dependence of the initial ice salinity on ice growth velocity and seawater salinity and also the subsequent drainage of brine from the ice. The equation for ice growth assumes a linear temperature profile within the ice and is driven by surface heat balance equations that are based on smoothed climatic data for the central Arctic Basin. based on smoothed climatic data for the central Arctic Basin The estimated salinity profiles are in good agreement with natural profiles. Although temperature and salinity profiles depend upon the time of the year when ice growth is initiated, the brine volume profiles which they specify are essentially a unique function of ice thickness; a conclusion that holds even when the insulative effects of snow are considered. The temperature and brine volume profiles are then utilized to calculate the ice strength and clastic modulus profiles, which in turn specify the composite mechanical properties of the ice sheets. Significant differences, which are largest for this ice sheets are observed between ice sheet properties or the ice sneets. Significant differences, which are largest for thin ice sheets, are observed between ice sheet properties as calculated using composite plate theory and properties calculated from uniform plate theory and average ice properties. These results provide a justification for the practice, common within the ice modeling community, of parameterizing the mechanical behavior of pack ice on the basis of the ice thickness distribution

RIVER.

Aerial reconnaissance of the ice regime over some 800 km of the Yukon River, from Lake Laberge to the U.S.-Yukon border, was carried out over two years. The paper describes the nature and rate of freeze-up and break-up progression observed in the two years, and the number and distribution of polynyas in mid-winter. The latter were found to be closely related to the presence of islands. Freeze-up progressed reasonably steadily over the whole reach after initial lodgement occurred some 700 km downstream of Lake Laberge. Break-up had a totally different character in the two halves of the reach: downstream it was rapid and dynamic; upstream it was slow and thermal. It is concluded that field observations are still essential to develop an understanding of the ice regime of a river reach. of the ice regime of a river reach.

STRENGTH, ICE STRENGTH.

To operate effectively in the cold regions, technology must be developed to contend with floating ice. Of particular importance are the morphology and physical properties of the tec cover. Long-term statistics on ice formation, growth, decay, ice extent, pressure ridges, etc., need to be obtained for areas of interest, theoretical models describing these processes need to be developed as well. Not only are such statistics required for U.S. and allied waters, but also for enemy waters where we may possibly operate, or at least assess the enemy's operating capability. Remote sensing of ice features and ice thickness from both aircraft and satellites is a means of obtaining ice statistics and rapid real-time measurements, additional studies on the electromagnetic properties of ice will enhance this capability. Constitutive laws and failure enteria need to be developed to solve analytical ice engineering problems. This requires that work on the mechanical properties of ice continue, with emphasis on multi-axial tests, tests at higher temperatures, and fracture mechanics. It is entical that any analytical work be supported by scale-model tests and full-scale field measurement programs. In all ice studies more attention should be given to the ice structure and the ice air and brine content. Without this information it is difficult to interpret the results and compare them to those of other investigators. Finally, conventional equipment should be tested in the field, evaluated for arctic applications, and, if accessary, redesigned

VEHICLES, SNOW COVER EFFECT, SOIL STRENGTH, TRANSPORTATION, MOBILITY, TRAFFICABILITY, TOPOGRAPHIC FEATURES, TRACKED VEHICLES, ENVIRONMENTS, WEATHER, CLIMATIC FACTORS, IMPACT STRENGTH.

In the arctic regions mobility of vehicles is frequently influenced more by the environmental (climatic) conditions than by the terrain. Weather has a profound effect on the performance of the vehicle, on the efficiency of the operator, and on the characteristics of the terrain, however, this effect produces mixed results. Mobility over many arctic terrains, such as muskeg, tundra with abundant lakes and meandering, braided streams, is greatly improved during the winter when the soil and water bodies are frozen and the terrain micro-relief features are masked by the snow cover. Thus, the arctic environment, while degrading the performance of people and machines, can be beneficial to the terrain trafficability characteristics. It is inonic, therefore, that as the environment becomes more pleasant for the people and the vehicles during summer it have an unfavora ble effect, due to thawing, on the trafficability of many types of arctic terrains. It can be generalized, therefore, that in the winter most mobility problems in the Arctic In the arctic regions mobility of vehicles is frequently in-

are caused by the environment (weather), while during the summer most mobility problems are caused by the terrain

MENT.
Research conducted on a wide variety of topics from habitability to roof leaks has played an important role in improving the design, construction, operation and maintenance of buildings and utilities in very cold regions. Documents such as the Cold Climates Utilities Manual have facilitated implementation of research findings. Other improvements have been the result of innovation by manufacturers and practicing engineers. Nonetheless, buildings are still being built that are uncomfortable or unsafe to live in Others have chronic moisture problems or deteriorate much more rapidly than expected. Pipes still freeze and effluent quality does not always meet standards. Additional research is needed since new materials, systems and processes are available that can solve some problems but pose others.

MATERIALS TEMPERATURE EFFECTS, FREEZE THAW TESTS.

Tests were performed to assess the effects of low temperatures Tests were performed to assess the effects of low temperatures (-50 C) and low temperature thermal cycling (10 cycles at -180 C to 24 C) on the mechanical properties of fiberglassepoxy and graphite-epoxy composite laminates. Results of these tests show various degrees of degradation of thematerials. At low temperatures, strengths associated with fiber-dominated modes of failure show decreases while those of matrix-dominated modes of failure show increases. Composites subjected to low temperature thermal cycling show strength reduction in matrix-dominated failure modes and strength increase in fiber-dominated modes. These results conform to the microcrack-growth-based damage mechanism of composite materials. composite materials.

YSIS (MATHEMATICS).

Knowledge of the growth of tee crystals in both wet and dry snow has evolved steadily over many years. Dry snow is characterized by rounded crystals growing slowly at low temperature gradients. Wet snow is characterized by clusters of grains at low liquid contents and poorly bonded slush at high liquid contents. Meti-freere cycles greatly influence wet snow as well. Information was first gained through field observations, then laboratory tests, and then physical modeling. Advances have been made through application of phase-equilibrium thermodynamics and knowledge of see crystal growth although much remains to be learned about the slow growth of tee crystals over a range of temperatures. The grain-to-grain nature of vapor flow in dry snow is complicated by the geometry of snow and this topic is being studied through stereology. Given recent advances in our understanding of snow metamorphism, a reclassification of snow seems necessary.

TURE VARIATIONS.
Dry snow, under the influence of strong temperature gradients, metamorphoses to depth hoar. This process requires a vapor flux through the snow, which can be driven by diffusion or convection. Convection in natural snow covers has been suggested but never previously detected. A three-dimensional array of 103 thermistors was monitored through the winter of 1914-85 to try to detect convection. A convection event lasting 8 days occurred in early winter during which large horizontal temperature gradients were measured. Because the snow was a nearly perfect, horizontally homogeneous layer, these temperature variations could only have been caused by convection. Analysis of possible sources of error in the temperature measurements, such as vertical misplacement of the thermistory, indicates that the observed temperature variations would have required uncervertical maplacement of the thermistors, indicates that the observed temperature variations would have required uncertainties in vertical position five times larger than were observed and thermistors that moved up and down with time. Rayleigh number calculations indicated that it reached its critical value only during the period in which the large horizontal temperature gradients were present and convection was occurrent.

WASTE TREATMENT, WATER TREATMENT, EVAPORATION, LAND RECLAMATION, WATER TEMPERATURE, MATHEMATICAL MODELS.

MODELS.

The removal of a number of trace organics from wastewater was studied on an outdoor prototype overland flow land treatment system.

For most of the substances, the observed removal rate could be described by the sum of two mass transport-limited first order processes representing volatilization and sorption. A model was developed by non-linear multiple regression analysis in which the observed removal rate constants were regressed against three properties of each substance—'Henry's constant, octanol-water partition coefficient and molecular weight.

The dependence of the removal processes on water temperature was also determined. removal processes on water temperature was also determined but not included in the initial model. The observed decrease in removal rate as the temperature declines is supported by the known dependence of Henry's constant and diffusivity n temperature.

TEMPERATURE, THERMAL INSULATION.
Laboratory tests were conducted with two full-size, two-phase commercial thermosyphons in an atmospheric wind tunnel at the U.S. Army Cold Regions Research and Engineering Laboratory. The test variables were air velocity maged from 0 to 5.2 m/s. The evaporator angles were varied from 0 to 5.2 m/s. The evaporator angles were varied from 0 to 1.2 de., measured from the horizontal. The effect of nearby walls on thermosyphon performance was also investigated. The air temperature for all tests was about 15 C. Test results are presented with thermal conductance of the thermosyphon as a function of air velocity and evaporator slope angle. The use of thermosyphons in a slab-ongrade foundation design on permafront was modeled using the finite element technique. Depth of thew within the fill decreases with increased thermosyphon conductance and increased insulation thickness. The simulations indicate that it is slightly better to place the thermosyphon evaporator vertically towards the fill base.

ROCK MECHANICS, STRESSES, MEASURING INSTRUMENTS.

This report summarizes the studies of the Vibrating Wire Stressmeter (VWS) in a high temperature environment in Climax granite considered for use as a nuclear waste repository. The study also included calibration tests of the meter in

The study also included calibration tests of the meter in Barre granite, aluminum, and Lucite under umanial, basial and triaxial stress fields. Biasial tests were performed by setting stressmeters into cylindrical rock cores loaded hydrostatically around their periphery, leaving the ends unloaded. Triaxial tests were conducted by repeating the basial tests, with the addition of end loading. The effects of temperature on calibration characteristics were evaluated by conducting uniaxial, biaxial and triaxial tests in the range from room temperature to 100 C. The results showed that the uniaxial stress sensitivity factor for a rock can vary over a wide margin. For Climax granite it varied from 2.7 to 4.5 The stressmeter setting preload has a major influence on the sensitivity factor and, to reduce this influence, an optimum preloading of the stressmeter must be ensured. The temperature rise increased the sensitivity factor under basial and triaxial loading significantly (up to 25%) but very little (less than 5%) under uniaxial loading. fup to loading.

The Cornish-Windsor bridge is the longest covered bridge in the United States and has significant historical value. Dynamic ice breakup of the Connecticut River can threaten the bridge and cause flood damage in Windsor, VT. We monitored ice conditions throughout the 1985-86 winter, observed a mid-winter dynamic ice breakup, conducted controlled release tests during both open water and ice cover conditions, and analyzed more than 60 years of temperature and discharge records. Biver templation presents afternatives. constitutions, and analyzed more tians so years or temperature and discharge records. River regulation presents alternatives for ice management that would minimize water levels during breakup. In this paper we develop the basis of a method to produce a controlled ice breakup at lower stage and discharge that occur during major natural events.

WEDDELL SEA.

Pressure ridges—the ice pileups above and below the ice surface that result from pack ice deformation—apparently contribute unique environments for the development of ice microbial communities. The significance of pressure-ridge communities to the total productivity of the pack ice is linked to the level of deformation resisting in increased ridge density of one region compared to another. In this article, two mechanisms are described which can lead to the development of microbial communities near pressure ridges. The first mechanism is associated with the instill ridge formation process which occurs during deformation periods in the intense reposs of the pack ice. The second effect arises after the ridges have formed and is related to flow breakup processes near the ice edge in the decay phase of the pack ice cycle.

RP-HPLC analytical methods were developed to determ trace levels of natrogramatics, natramines, tetratene, and ne-

troguanidine in soil and water. The method to determine nitrogramatics and nitramines in soil has been thoroughly tested with soils from a wide variety of sites, and it has been found to be reliable and inexpensive to implement. A full-scale collaborative test proved that acceptable performance enteria were attainable in everyday use. Methods for tetrazene and nitroguanisme have not been evaluated by a full-scale collaborative test because few areas need to be tested for contravination by these commonsts. Methods to be tested for contamination by these compounds. Methods will continue to be deseloped at CRREL as the need arises for other military-unique compounds.

ICE SHEETS, ICE MODELS, ICE DENSITY, DATA PROCESSING, RADAR.

DATA PROCESSING, RADAR.

A method for calculating the impulse response of a layered defective is used to investigate the effect of near-outlace density stransfeation on the interpretation of radia-altimetry data collected over see sheets. Results are compared for a model consisting of a measured density profile that is artificully interrupted by an see layer morted at successively greater depths. The impotent radar signal is modeled by a 10 ns long pulse modelated at 1 GHz. Analysis using a simple scheme for estimating the one-way travel time of the wave inductive as much as a 2 ns (expandent to 60 cm in range) apparent time delay for a density profile that has been modeled by inclusion of an ice layer relative to the ice-layer-free case. This suggests that layering may be a factor in interpreting repeated altimeter measurements of the ice sheets in terms of net growth or decay. (Auth.)

The U.S. Army Coeps of Engineers specifies low viscosity or commonly called "soft grade" asphilts for use in cold reports. These soft grade asphilts are premarily used for controlling low temperature cracking in some ports of northern U.S. and Canada. The Coeps, besides specifying the usual asphilt specifications, also defines the allowable temperature susceptibility of the asphilt using the Penetration Viscosity Number (PVN) index. It specifies a monomous PVN of 40.5 in moderately cold areas and 40.2 in regions where the design freezing index is greater than 1000 day F days. Field studies have been conducted that clearly show the benefits of using soft grade asphilt for minimizing low temperature cracking in cold regions, however, field studies relating ruring to asphilt type are scarce. A major concern is whether or not soft grade asphilts are susceptible to retine during the hot summer months. A literature review and field study was conducted by the U.S. Army Cold Regions Research and Engineering Laboratory (USACRRELL) on the performance of pasements constructed with soft grade asphilts. The results of the literature review and field studies are presented in this paper. presented in this paper

EMATICS).

Pressure buildup due to internal freezeback of saturated sand in permafrost pile supports should be considered in the design of pile support casings. The internal pressure buildup is caused by nonuniform freezing resulting from seasonal temperature variations and the fact that the pile supports are partially buried in permafrost. An analytical elastic model is developed to determine the internal freezeback pressure in the support casing resulting for a top concrete sealer or plug is also studied.

Different internal freezeback geometries are considered to simulate the freeze-

back process of the early design consideration of filling the casing with saturated sand fill The computed results are compared with the allowable shear resistance of the concrete scaler. With a completely saturated and confined concrete sealer. With a completely saturated and confined system, the freezeback pressure exerted on the casing and the concrete sealer is significant for all freezeback geometries. The results indicate that an undersaturated sand fill or a saturated fill only to the ground level with an air cap should be used to protect both the casing and the concrete sealer

MILITARY RESEARCH, TESTS.

The US Army Cold Regions Research and Engineering Laboratory has a new controlled-environment test facility, the Frost Effects Research Facility (FERF), now in use The 29,000-sq foot (2694-sq m) building comprises a principal test area 182 ft long by 45 ft wide (56 m by 138 m) that incorporates 12 test basins, adjacent mobilization areas, and equipment rooms, for a total width of 102 ft (31.4 m) plus fully enclosed ramp areas at each end of the building Surface panels are used to freeze pavement and soils for the pavement, utility, soil scnsor, and mobility test programs Liquid-to-air heat exchangers are used to test hardware inside enclosures erected in the test basins or on the mobilization area. Currently, coolant is available at -37 F, 0 F, and +100 F (-38 C, 017 8 C, and 37.8 C), allowing test temperatures ranging from -35 F to 90 F (-37 C to 415 C). Lower temperatures can be achieved by using portable units in conjunction with the facility's permanent system.

DEEP FROST EFFECTS ON A LONGITUDINAL EDGE DRAIN.

Allen, W.L., International Cold Regions Engineering Specialty Conference, 5th, St. Paul, MN, Feb. 6-8, 1989. Proceedings Edited by R.L. Michalowski. Cold regions engineering, New York, American Society of Civil Engineers, 1989, p.343-352, 2 refs. 43-2115

SNOWMELT.

During the summer of 1986, a 2900-ft (883.88-m) long runway, a taxiway and a parking apron were constructed at Newton Field in Jackman, ME. The runway pavement section consists of 2-1/2 in (6.35 cm) of asphalt concrete, 12 in (30.5 cm) of base course, 2 in (5.08 cm) of extracted polystyrene insulation and a 1-in. (2.54 cm) sand leveling course. The structure is sloped to drain to a 5 to 7-1/2 ft (1.52 to 2.29 m) deep longitudinal edge drain on the north side of the runway. Jackman has a design freezing index of approximately 2570 F-days (1428 C-days). The subgrade soil is a sandy, silty, clayey material of significant frost susceptibility. The water table at Newton Field is relatively shallow, increasing potential frost and drainage problems. Temperature sensors were installed during construction and temperatures in the pavement structure were monitored during the winter and spring of 1986-1987, 1987-1988. In the summer of 1987, a were was installed to monitor the flow from the outlet pipe fer about one-flow from the outlet pipe fer about one-flow form the ou ness of the system in a frozen or partially frozen state

One possible cause for winter mortality of salmonids is freezing of the bed material where the fry and parr are residing in a dormant state. Typical habitat reaches in streams of the White Mountains of New Hampshire and the Green Mountains of Vermont were established as study sites. The sites averaged 200 m long, ranged in width from 10 to 30 mi, and represented channel configurations of riffle, run, pool and cascade. The interaction of ice with different channel geomorphic configurations was examined. Winter monitoring techniques included magnetic induction conductivity, high-frequency rader and hand augers to acquire ground truth data. The freeze-up processes were documented with 35-mm photography.

PRELIMINARY RESULTS OF AN EXPERIMENT USING A 16 FT X 50 FT LONG FRAZIL COLLECTOR LINE ARRAY.

Perham, R.E., Workshop on Hydraulics of River Ice-/Ice Jams, 5th, Winnipeg, Manitoba, June 21-24, 1988. Proceedings, (1988), p 139-156, 9 refs. 43-2169

A line array 16 ft wide x 50 ft long was tested in a small vermont mountain river late in 1980 to determine its ability to form a surface ice cover during the period when the site would normally remain as open water. Though it had little effect on the overall ice cover development on the river, a stable ice cover formed a week or so earlier on the line array. Site characteristics were seen to affect the line array. Water velocities adjacent to the lines were measured and varied from 2.3 to 3.6 ft/s. By Dec 30 solid ice thickness on the array varied from 1.13 to

1.33 ft, which would be typical of lake ice for the same

ICE BREAKUP, VELOCITY.

While the potential for scouring of a river bed during an ice jam event has often been cited as a cause for concern in association with pipeline crossings, bridge piers and other hydraulic structures, almost nothing is known about the subject Significant changes in the river bed might also influence the formation of the jam itself and the water levels that result. This paper describes preliminary flume experiments to examine the effects of a floating accumulation of ice in a movable bed channel. The experiments consisted of establishing a uniform free-surface open channel flow just below the threshold of bed motion, and then installing artificial ice jams of assumed geometries and monitoring the resulting scour patterns

TRANSVERSE VELOCITIES AND ICE JAM-MING POTENTIAL IN A RIVER BEND. Zufelt, J.E., Workshop on Hydraulies of River Ice/Ice Jams, 5th, Winnipeg, Manitoba, June 21-24, 1988. Proceedings, (1988), p.193-207, 6 refs.

ICE JAMS, RIVER ICE, RIVER FLOW, TOPO-GRAPHIC EFFECTS, STREAM FLOW, VELOCI-

River bends have been reported as major locations for the initiation and development of ice jams. Bends are characterized by nonuniform channel cross sections with velocity fields affected by centrifugal acceleration. The alterations to the streamwise and transverse velocity fields are factors influencing the initiation and development of ice jams in river bends. The streamwise and transverse velocity distributions river bends The streamwise and transverse velocity distribu-tions through a river bend were examined in order to assess ice jamming potential. Tests were conducted under open water, and smooth and rough artificial ice cover condutions. The effects of the above variables on the streamwise and transverse velocity profiles in a river bend are discussed

43-2280 RIVER ICE, FRAZIL ICE, ICE GROWTH, ANI-MALS.

Literature describing the winter habitat of Atlantic salmon (Salmo salar) is reviewed Causes of winter mortality of salmonids are proposed. Four factors considered detrimental to overwinter survival include 1) crowding of juveniles mental to overwinter survival include 1) crowding of juveniles into smaller areas due to freeze-up ice cover formation and reduction of available habitat, 2) migration of fish due to overcrowding, 3) solid ice growth into the substrate, thereby freezing the redds and the juvenile fish, and 4) high velocity flows that occur during ice cover breakup and ice jam releases. An analytical treatment of the ice front progressing into the substrate is presented and a realistic example is given to confirm the hypothesis that the freezing of redds is a high potential source for egg and juvenile losses. Frazil ice accumulation under the ice cover on the bed is detrimental to salmonid survival because it accelerates solid ice growth. Increases in overwinter survival have been shown to be Increases in overwinter survival have been shown to be directly linked to the amount of adequate winter shelter includes two key elements: silt-free rubble substrate and adequate flows

This paper describes a clamping system that provides a means to alternate freely between tensile and compressive uniaxial loads on an ice specimen. The fixture is hydraulically activated and is used in conjunction with a closed-loop testing system. It is self-aligning, holds the specimen rigidly in place and imparts no detectable bending moment to the specimen when it is activated. The testing methodology centered on this device has proven to be very efficient and reliable. Results of several of the initial experiments employing this device are also presented. These include examples of the effect of loading frequency and grain size on hysteresis, the effect of strain level on the secant modulus for both tensile and compressive loading and an example of tensile failure following compressive loading in a regime characterized by a high degree of microcracking

ON MODELING THE ENERGETICS OF THE RIDGING PROCESS.

Laboratory tests were conducted on floating freshwater ice sheets reinforced with a high-strength polymene mesh (Geogrid). The mesh was frozen into the ice sheets because the tests were conducted on each ice sheet thickness of the ice sheets varied from 3 to 13 cm and the dynamic loads varied from 1 3 to 23 kN. Compansons to tests on ice without the grid were made. For the ice sheets tested, Geogrid reinforcement increased the baringe capacity of thin (49 mm) ice up to 38% and of thicker ice (96 mm) about 10-15%. Failure of the ice with Geogrid reinforcement was very local, whereas failure of the ice without Geognd was catastrophic and over a large area. Displacement of the ice is compared to theory for plates on an elastic foundation. an elastic foundation.

MATION.
Floating model (urea) ice sheets were penetrated vertically up with cylindrical indentors of different shapes (flat, truncated-conical and conical) and diameters (76 mm, 152 mm and 305 mm) and in different ambient temperatures (0, 10, 20 F). Our experimental results show that there is no effect of indentor shape or size on the ice penetration forces. From dimensional analysis, a relationship is obtained for maximum ice penetration force in terms of the specific weight of water, the ice thickness and the upward flexural strength. From the measured deflections of the ice sheet at a few points along a radial line during penetration tests, the buoyancy force is calculated independently of the total measured force, by subtracting the buoyancy force from the total measured force, the inertial force is obtained. Plots of these forces are given for a few tests

TARCTICA—ROSS SEA.

At the end of the 1980 austral winter, surface roughness measurements were made by laser profilometer during a senes of flights over the Ross Sea pack ice. The total track length was 2696 km, and 4365 ridges were counted the frequency distribution of individual ridge heights was found to be well described by a negative exponential distribution. No clear-cut regional variation was noted in ridge heights. The distribution of ridge frequencies per kilometer showed a strong positive skew with a modal value of 188, the most freque ridging occurred off the east coast of Victoria I and Comparisons with similar data sets from the Arctic indicate that large ridges are significantly more likely in the Arctic Ocean than in the Ross Sea. Utilizing a reasonable model for the geometry of ridges, estimates are made of the average thickness of a hypothetical continuous layer composed only of the deformed ice from ridges. The noncoastal Ross Sea value of 0.09 m is less than half of the lowest comparable value from the Arctic. (Auth mod)

EMATICS).

A series of 30 fracture toughness tests were performed on aboratory-grown S2 columnar freshwater uce at high homologous temperatures (-2 to 0 C)

The floating double cantilever beam specimen used and the monitoring of the crack mouth opening displacement in addition to the applied load provided a means for obtaining an apparent fracture toughness, an effective clastic modulus, a lower-bound estimate of the crack speed, and a side-loaded flexural strength of the ice. An expression for the apparent fracture toughness as a function of the applied load, specimen geometry, and ice thickness was developed using a finite clement program. Total sllowed comparison with previously published values for the toughness of freshwater ice. The small range of scatter in apparent fracture toughness values as well as the ability to measure other mechanical properties of the ice indicates the usefulness of such tests.

NUCLEATION, ICE RELAXATION, TENSILE PROPERTIES, GRAIN SIZE, MATHEMATICAL MODELS, TEMPERATURE EFFECTS.

MODELS, TEMPERATURE EFFECTS.

This paper describes the development of a model for the flexural strength of S2 freshwater ice in simple bending under isothermal conditions. The model applies to the case of nucleation-controlled failure and addresses temperature and grain size effects. The derivation balances the energy supplied by stress relaxation with the energy required to overcome the barrier to crack nucleation and the energy to form new surface area. The nucleation barrier, which is not yet fully specified, can be determined from experimental results and appears to be independent of temperature for the flexural case under consideration. The physical reasoning behind the model leads to a mathematical form that differs somewhat from the expression generally used to represent similar experimental results. The conceptual basis for the model draws from observations on the flexural tests, from published microscopic observations for ice and from the literature on nucleation theory. The model predictions compare favorably with published experimental results for the flexural strength as a function of temperature in the range of -1 to -19 C and as a function of grain size in the range of 0 0002 to 0 006 m.

MP 2495 RESULTS FROM INDENTATION (ESTS ON FRESHWATER ICE.

Nakazawa, N.

IMPACT TESTS, TENSILE PROPERTIES, COM-PRESSIVE PROPERTIES, ICE PRESSURE, VELOCITY, EXPERIMENTATION.

VELOCITY, EXPERIMENTATION. Indentation tests were performed by pushing vertical, flat indentors of 50- and 100 r-m widths into freshwater columnar ice of different thicknesses (25-60 mm) at different velocities (1-9 mm/s). Extensive data on forces, displacements and acoustic emissions were recorded, and some of these are presented in this paper. Depending on the velocity of the indentor, ductile or brittle behavior of ice was observed. A few attempts to measure the pressure at the interface during ice crushing indicated a uniform pressure distribution. Later in the program, the interaction forces were measured at the ice-structure interface by supporting indentor plates on three load cells. With this system, the j ints of action of the resultant forces were found to be in the center of the contact area, indicating uniform pressure distribution. MP 2406.

HIGH-FLOW AIR SCREENS REDUCE OR PRE-VENT ICE-RELATED PROBLEMS AT NAVIGA-TION LOCKS.

ICE BREAKING, ICEBREAKERS, SHIPS.

This paper describes the second phase in the development of a river ice-prow intended to be attached to a towboat for opening navigation channels or for ice management in the vicinity of the locks and dams on the northern rivers of the United States (Illinois, Ohio, and Upper Mississippinvers). The first prow concept, presented at the 1986 IAHR [cc Symposium in lowa City, proved during model tests to be less maneuverable than desired. Most of the difficulties were attributed to the side ice-cutters and to a poor lengthwise weight distribution. The be "was redesigned and the side cutters were eliminated. Model tests showed greatly improved maneuverability in ice without significant effect on the icebreaking capability of the prow. The results of these tests are presented and discussed.

ICE COVER FORMATION DOWNSTREAM OF A LARGE RESERVOIR WITH VARIABLE RE-

Ashton, G.D., IAHR Symposium on Ice, 9th, Sapporo, Japan, Aug. 23-27, 1988. Proceedings, Vol.2, Japan, Aug. 23-27, 19 [1988], p.189-198, 3 refs. 43-2992

DAMS, RESERVOIRS, ICE FORMATION, ICE COVER, ICE CONDITIONS.

COVER, ICE CONDITIONS.

On the Missouri River, downstream of Oahe Dam, an ice cover forms, accumulates and retreats in response to varying air temperatures, varying and daily peaking discharges of up to 1400 cu m/s, and varying water temperatures of the release. Extreme accumulations of this ice in some years have caused flooding due to the increased stage associated with the resistance of the ice cover. A simulation of the accumulation and retreat of the ice cover has been constructed, including the variability of the discharge, water temperature, and air temperatures, and compared and calibrated against available data. A discussion of the various approximations used in the simulation is presented together with an assessment of the improvements that occur when various parts of the simulation are treated in more detail, such as using hourly energy budgets rather than daily averages based on a simple bulk heat transfer coefficient

EFFECTS OF AN ICE COVER ON FLOW IN A

MOVABLE BED CHANNEL.
Wuebben, J.L., 1AHR Symposium on Ice, 9th, Sapporo, Japan, Aug. 23-27, 1988 Proceedings, Vol.3, 1988, p.137-146, 3 refs.

WATER FLOW, CHANNELS (WATERWAYS), SEDIMENT TRANSPORT, ICE COVER EFFECT, ALLUVIUM, FORECASTING.

ALLUVIUM, FORECASTING.

The formation of an ice cover on an alluvial system results in significant changes in the flow regime due to the interaction between the ice cover, fluid flow, fluid properties, sediment and bedforms. For the case of uniform flow in a rigid channel, the addition of an ice cover of uniform thickness and surface roughness would typically result in an increase in water depth and a reduction in water velocity and bed shear. Such a flow can be conceptually split along a hypothetical plane of zero shear located approximately at the point of maximum; velocity in any vertical profile If this concept could be extended to flow over a movable bed, then existing free surface sediment transport theory could be applied to the lower layer by treating it as a distinct "open channel" case. To test the practicability of using this lower layer approach to predict sediment transport and resistance to flow in an ice covered channel, a series of tests were conducted at various discharges in a laboratory flume. The sediment was a uniform, 0.45-mm-diameter quartz sand and bedforms were in the ripple and dune regimes. For each discharge, a run was initiated by establishing uniform flow under a simulated ice cover. Once the lower layer depth and discharge were determined, a corresponding open water flow was established leaving other parameters unchanged. The ice covered and free surface flow were then compared based on sediment discharge, bed form geometry, and energy slope to determine the applicability of the lower layer approach. ometry, and energy slope to determine the applicability the lower layer approach

MP 2500 FORECASTING RIVER WATER TEMPERA-

Daly, S.F., IAHR Symposium on Ice, 9th, Sapporo, Japan, Aug. 23-27, 1988 Proceedings, Vol.3, 1988, p.180-188, 6 refs. 43-3031

FORECASTING, WATER TEMPERATURE, WATERSHEDS, AIR WATER INTERACTIONS, RIVER ICE, MATHEMATICAL MODELS.

The water temperature of a river at any point reflects how the upstream waterahed responds to heat transfer with the environment. The ability to model this response provides a way to forecast future river water temperatures, which could be an important part of an ice forecasting program. This paper presents a model of the watershed response. In the model the overall environmental heat transfer is calculated based on two terms one linearly dependent on the difference between the water and air temperature. The response of the watershed is determined by analyzing the past records of air and water temperature. From these records, monthly of air and water temperature from these records, monthly or seasonal response coefficients for the watershed are determined. Forecasts of future air temperature, along with the known water temperature at the time of the forecast, are used to forecast water temperature. Water temperature the known water temperature at the time of the forecast, are used to forecast water temperature. Water temperature can be forecast for any future data, however, in practice the accuracy is limited by the current limitations of air temperature forecasts. The model is applied to the Ohio River, and results are shown as hindcasts of water temperature based on the actual recorded air temperatures, and hindcasts of "likely ice periods" based on the actual recorded data. The model can be used to forecast likely ice periods in large and small watersheds, is designed to be used with real-time water temperature measurements and is particularly useful for forecasting tributary water temperatures as boundary conditions for more elaborate models. conditions for more elaborate models

MP 2501 LABORATORY STUDY OF TRANSVERSE **VELOCITIES AND ICE JAMMING IN A RIVER** BEND.

poro, Japan, Aug. 23-27, 1988. Proceedings, Vol.3, 1988, p.189-197, 6 refs. Zufelt, J.E., et al, IAHR Symposium on Ice, 9th, Sap-

RIVER FLOW, SIMULATION.

The velocity field through a river bend is greatly affected by its channel curvature, primarily by the action of centrifugal acceleration. The streamwise velocity gradient is responsible for a nonuniform distribution of centrifugal forces, which results in a radial circulation. River bends have long been reported as the locations for the initiation and development of ice jams. These radial velocities affect the transport and deposition of bed material and/or ice in the bend, resulting in nonuniform depths and ice thicknesses over a cross section. The streamwise and transverse velocity profiles through a 90 deg bend of a laboratory flume were examined. A variety of discharge, bed roughness, and water surface conditions were tested, including smooth and rough simulated ice covers. The effects of each variable on the velocity field were identified. rough simulated ice covers. The eff on the velocity field were identified

ICE CRYSTAL STRUCTURE, GEOCHRONOLO-GY, ANTARCTICA—ALLAN HILLS.

While searching for meteorites in the Allan Hills region during the austral summer of 1982-1983, a small, walnutsized meteorite was discovered with just its tip protruding above the ice surface. The meteorite appeared to be still embedded in the original ice and becoming exposed for the first time at the ablation surface. If this interpretation were proved correct, this would be the first example observed in Allactics of an expression store, a discovery of secret. were proved correct, this would be the first example observed in Antarctica of an energing stone, a discovery of special importance because the terrestrial age of the meteorite would be the same as that of the enclosing ice. This study was undertaken to determine if the crystalline properties of the ice were consistent with the notion that the ice enclosing the meteorite is coeval with the terrestrial age of the meteorite. Following remeasurement and photography the ice block was split apart by wedging and the meteorite removed. The ice was then cut in three mutually perpendicular directions in order to evaluate the three dimensional picture of the crystal/bubble structure of the ice. It is concluded from the analysis that the meteorite was, in fact, just emerging at the ablation surface when it was discovered. (Auth.)

PORTABLE SHELTERS, MILITARY FACILI-TIES, COLD WEATHER TESTS. The US Navy has designed and initiated procurement of

The US Navy has designed and initiated procurement of more than 20 modular, containerized fleet hospitals ranging in size from 250 to 1000 beds. The hospitals are tenthased but include specially outfitted hard shelters for operating rooms, labs, and other hospital functions. Interconnected tent wings comprise the wards, casually receiving, and some administrative functions. Hospital staff are housed in general purpose tents. Piped water and wastewater systems are provided in the hospital. All wards and outfitted shelters are provided with electrical, heating, and air-conditioning equipment. All hospital components were designed to operate within a temperature range of +125 F to -10 F, but the lower end of this range had not been evaluated under actual winter conditions. At the request of the Navy's Fleet Hospital Program office, representative sections of a fleet hospital were tested at CRREL from Dec. 1986 through May 1987. The hospital was instrumented with approximately 100 thermocouples, and temperatures were recorded every 3 hours throughout the test period. Extensive weather records were collected by an on-site meteorological station. Several subsystem failures were identified and documented, primarily in the heating, electrical, and wastewater facilities. Modifications were made to the plumbing and heating systems in an effort to correct identified failures or to improve the effectiveness of the systems.

ARTIFICIAL FREEZING, WASTE TREATMENT, SOIL FREEZING, SOIL POLLUTION, WASTE DISPOSAL, SOIL WATER MIGRATION.

Laboratory, methods were developed to demonstrate and evaluate the feasibility of using artificial soil freezing as a costeffective technique in general site decontamination. This
effort is part of CRRLL's artificial freezing research program
for hazardous waste management. The study attempted
to quantify parameters which influence contaminant transport in voils during freezing. Among the influence contaminant ransport in voils during freezing. Among the influencing parameters, freezing rate was found to be the most significant. Contaminant movement profiles in soils during freezing were measured Laboratory column studies showed a significant mobility of volatile organics, such as benzene, chloroform and toluene, when Lebanon sity soil contaminated with these organics was frozen from the bottom up. A range of 25-67% reduction in contaminant concentration was measured in

the frozen soil sample when subjected to an average freezing rate of 0.25 cm/day, with the concentration increase found just around the freezing front. However, a corresponding 25-67% increase in concentration ahead of the freezing front was not obtained as expected, due to contaminant losses through volatilization, biodegradation and sorption. A mathematical contamination of the production of the product through volatilization, biodegradation and sorption. A matan-ematical correlation was established between the contaminant relative change in concentration and their octanol-water parti-tion coefficients. The well-correlated relationship strongly suggests the dependence of the freezing-induced mobility of the specific organic contaminant component on its octanol-water value.

SOIL WATER MIGRATION.

Recently, artificial freezing has been identified as a potential and plausible technique for treating soil contamination as well as for general site decontamination. As part of the overall CRREL artificial freezing research program for toxic and hazardous waste management and control in cold regions, a large-scale prototype testing facility has been constructed to study and evaluate contaminant movement in soils during freezing. The contaminants proposed to be used for the study include volatile organics, such as chloroform, toluene, and benzene, and non-volatile organics, such as TNT and RDX. Variation in contaminant concentration during freezing would be obtained by soil coring and sampling tubes in different locations. Contaminant concentration would be determined using a gas chromatograph/mass spectrometer and high-precision liquid chromatograph.

WASTE DISPOSAL, SOIL WATER MIGRATION, EXPLOSIVES.

In the past few years, CRREL has been investigating the use of artificial freezing as an innovative technique for soil decontamination. A preliminary laboratory study was conducted specifically to evaluate and analyze the possibility of mobilizing different types of contaminants by freezing in Lebanon silt. Contaminants investigated were explosive residues most extensively found at the U.S. Army ammunition lants as well as volatile organic compounds (VOC3), such as chloroform and toluene. Explosives studied were 2,4,6-trinitrotoluene (TNT), hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), octahydro-1,3,5-ternanitro-1,3,5-tertazione (HMX), 2,6-dinitrotoluene (2,6-DNT), ortho-nitrotoluene (O-NT), and meta-nitrotoluene (A-NT) Preliminary data from the laboratory column studies suggested that there was a certain degree of movement of both explosives and VOCs when soil columns of Lebanon silt saturated with these contaminants were frozen unidirectionally from the bottom up. Slopes of the control and frozen soil concentration profiles were statistically analyzed and a comparison between them was made. One freeze cycle at an average freezing rate of 0.5 cm/day was used. Insignificant amounts of movement (<10% change) were observed for 2,0 DNT, O-NT, M-NT, toluene and chloroform For given freezing rate, freeze-thaw cycles, soil and moisture content, it was hypothesized from this and other previous experimental data that the ability to move any contaminant by freezing strongly depends on the type, initial concentration level and the soil/chemical interaction of the contaminant.

MP 2516 VIBRATING WIRE TECHNOLOGY FOR SET-TLED DUST MONITORING.

Dutta, P.K., et al, Battlefield Dust Environment Symposium, 3rd. Proceedings, edited by R.R. Williams and R.E. Davis, [1988], p.71-82, 2 refs. Runstadler, P.W.

44-282 DUST, DETECTION, REMOTE SENSING, MEA-SURING INSTRUMENTS.

A new remote operating sensor for accurate and continuous monitoring of dust settlement rate is described. The system was developed for monitoring settled dust in underground coal mines, but it is conceived that it can also be used

for monitoring dust deposition in many other situations. The design is based upon vibrating wire technology, which makes the device insensitive to lead wire resistance, contact resistance, ground leakage, and humidity, which are common instrument problems in any field environment. The portable readout is microprocessor based, and can read up to 10 remote sensors connected through a switch module. Dust loading on the sensors is read directly in mg/sq cm. In use, the 10 sensors can be placed at various locations, and all can be monitored with their cables terminating at a central station where the switch module is located. The maximum permissible distance of the sensors from the readout is about 1.6 km. The readout unit weights 4 kg and is rugged and splash-proof. Both the sensor and the readout unit were tested for shock and vibration, and both met military standards. The sensors are temperature compensated and can detect changes in dust loading as small as 0.5 mg/sq m. The total range of the sensor is 0 to 500 mg/sq cm. The paper describes the principle by which the sensors operate, the assembly procedures, and the results of sensor calibration, stability and repeatability tests. The details of the readout unit are also described.

WAYS, DRILLING, GRAVEL, SEASONAL FREEZE THAW, SANDS. The U.S. Geological Survey (USGS) has been charged with the responsibility of evaluating the petroleum potential of the National Petroleum Reserve in Alaska (NPRA). This work had already been initiated by the US Navy, from whom the NPRA was transferred to the Department of the Interior. To help fulfill its responsibility, the USGS in Feb 1977 started an engineering geology program to provide the geotechnical support necessary for the exploration program. The USGS requested the U.S. Army Waterways Experiment Station (WES) at Vicksburg, MS, and the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) at Hanover, NH, to conduct studies to obtain the physical parameters required to evaluate and solve some of the geotechnical and engineering problems. All of the NPRA is underlain by permafrost, and thus virtually all of the engineering and geotechnical problems encountered during the construction of the well sites and subsequent drilling were associated with permafrost. The widespread occurrence of permafrost containing large amounts of near-surface ground ice in the form of wedges, masses, and intergranular ice required that construction activity not disturb the thermal regime of the ground surface, because such disturbance could lead to thawing of permafrost. Once the permafrost was thawed, ground subsidence, sediment flow, and impassable conditions would result. Construction problems were compounded by the necessity that all construction in the NPRA be done during the winter months to meet the environmental requirements. Therefore, the engineering geology program consistently addressed the impact of the environment on the facilities and the effect of the facilities on the environment

CIAL HYDROLOGY, UNITED STATES—ALAS-KA—STRANDLINE LAKE.

Jökulhlaups, or outburst floods, have occurred every 1 to 5 yr from Strandline Lake, one of the largest glacier-dammed lakes in North America. They flood the Beluga River, which was once in an undeveloped region but now is spanned by bridges and power lines leading to Alaska's largest urban area. In 1982, a study of the mechanisms that produce these jökulhlaups was initiated to improve the ability to predict them and thereby to mitigate their damages. Reliable precursors appear to be development of a distinct calving embayment in the lobe of the Triumvirate Glacier, which dams Strandline Lake, and formation of a number of supraglacier pools. Contour maps made from photos taken immediately before and after the jökulhlaup of Sep. 17, 1982 indicate that over 95% of the lake drained, releasing about 700,000,000 cu m of water. The lake is dammed by a glacier lobe that fractures and subsides during a jökulhlaup, which indicates that the release mechanism is hydrostatic lifting of ice off a subglacial spllway; the exposed areas surrounding the glacier margins suggest that the spillway may be controlled by bedrook. Large variations occur in the refilling period of Strandline Lake. Modifications of subglacial drainage into Strandline Lake as a result of jökulhlaups, combined with complex sub- and marginal drainage patterns, appear to exert controls which are not understood but which contribute to the variable filling rates.

PROPERTIES, FLEXURAL STRENGTH, CONCRETE AGGREGATES, CONCRETE CURING.

PROPERTIES, FLEXURAL STRENGTH, CONCRETE AGGREGATES, CONCRETE CURING. This report discusses laboratory engineering tests that were performed to determine the properties of polymer concrete under cold conditions. The polymer tested was Percolosed, a three-part polyurethane resin, catalyst amounts were adjusted so that samples set at approximately 30 seconds. The 11 conditions tested involved variations of three factors: (1) ambient temperature (35, 15, 0, or -20 deg F); (2) cure time prior to testing (30 minutes or 24 hours), and (3) moisture content of the aggregate (dry or wet). Flexural strength was determined at all conditions. Tests of compressive strength, chord modulus of elasticity, and Poisson's ratio were performed at each temperature on samples prepared with dry aggregate and cured for 30 minutes. Results of the compressive strength, flexural strength, and modulus of elasticity tests, which all decreased with temperatures from 35 to 0 deg F, but dropped off sharply at the -20 deg F condition. Samples prepared with wet aggregate had much lower flexural strengths than samples prepared with dry aggregate and met the minimum requirements only at the 35 deg F condition. Poisson's ratio, which increased with colder temperatures, remained within the specified range at 35 deg F condition. Poisson's ratio, which increased with colder temperatures, remained within the specified range at 35 deg F and 15 deg F and exceeded the specifications at colder temperatures.

STATISTICAL ANALYSIS.

It is well known that lightning bolts trace a zig-zag course between clouds or from cloud to ground. This course is apparently determined during the development of "leader strokes" through which the bolt advances. This paper proposes a model for the development of such a leader stroke. Assumptions used in this model are: 1. A uniform global electric field exists between cloud and ground or cloud and cloud. 2. Electric cells of various strengths and sizes are randomly distributed in the vicinity of the tip of a leader. 3. An electric charge is supplied to the tip of the leader stroke through the previous stroke to increase the electric field around the tip. 4. When the field strength between the advancing tip and one of the cells becomes strong enough, discharge between the tip and the cell takes place, advancing the leader stroke to the cell. Monte Carlo computer simulation of such a model in two and three dimensions has produced patterns to the cell. Monte Carlo computer simulation of such a model in two and three dimensions has produced patterns with a straking resemblance to published photographs of lightning bolts. Statistical analysis of the data generated by the simulation produced by changing various parameters indicated that certain information can be gained by analyzing those photographs For instance, an increase in general electric field strength results in a less tortuous track with longer steps, while a larger cell size distribution results in more ragged tracks

By comparing the statistical analysis of lightning stroke shapes obtained from photographs with observed field conditions causing the strokes, various parameters such as field strength and cell size could be estimated.

MP 2525 GEOTEXTILES AND A NEW WAY TO USE THEM.

Henry, K., Society of Women Engineers. National Convention and Student Conference, Puerto Rico, June 20-26, 1988. Proceedings, [1988], p.214-222, 44-470

SOIL WATER MIGRATION, FROZEN GROUND MECHANICS, FROST HEAVE, FILTERS.

MECHANICS, FROST HEAVE, FILTERS.

This study utilizes soil specimens prepared with geotextiles subjected to unidirectional standard frost heave tests Results indicate that geotextiles can reduce frost heave. Characteristics that influence capillary behavior include pore size distribution and structure of the fabric as well as surface properties of the fibers. Furthermore, fabric thickness appears to influence performance as a capillary barrier. Currently, little is known about fiber surface properties and there are no standard tests to evaluate characteristics such as wetting angle. Test observations indicate the importance of quantifying fabric pore size and the wetting angle of fibers in the fabric so that their influence on capillary behavior can be quantified.

THEORY FOR A TWO-WAVELENGTH MEAS-UREMENT OF THE PATH-AVERAGED TURBU-LENT SURFACE HEAT FLUX.

Andreas, E.L., Lower Tropospheric Profiling: Needs and Technologies, Boulder, CO, May 31-June 3, 1988. Proceedings, [1988], p.219-220, 9 refs.

44-421 FLUX, MEASUREMENT. SURFACE ROUGHNESS, ANALYSIS (MATHEMATICS).

ROUGHNESS, ANALYSIS (MATHEMATICS). Eddy-correlation, inertial-dissipation, flux-gradient, or bulk-aerodynamic methods—the traditional micrometeorological ways of measuring the turbulent surface fluxes of momentum and sensible and latent heat—all yield point estimates of the fluxes. Even over surfaces that are only slightly inhomogeneous, however, such point estimates can be unrepresentative of average surface conditions. Wyngaard and Clifford (1978) and Coulter and Wesely (1980), among others, have therefore suggested that path-averaging electro-optical systems could be used to obtain surface-averaged fluxes, but until now no one has shown how to obtain both sensible and latent heat fluxes from path-averaging instruments without the necessity of also making some point measurements. A two-wavelength, electro-optical technique is described that can yield path-averaged sensible and latent heat fluxes without requiring associated point measurements

WATER SUPPLY, REMOTE SENSING.

WATER SUPPLY, REMOTE SENSING.
In the past 5 years there has been rapid advancement in the use of remote sensing in the area of water resource management. Satellite image data are now available from operational systems such as the NOAA and SPOT satellites In addition the Landsat series of satellites have taken data over a major portion of the globe. Many procedures and methods have been developed to analyze digital satellite data but the techniques to use them operationally for evaluating water resources on a global scale are in their infancy. A discussion of the methods used by the Corps of Engineers to address water related topics is presented to illustrate how world communities must learn to use remote sensing for collection of data required to manage their water resources.

RIVER ICE, ICE BREAKUP, ICE JAMS, RIVER FLOW, ICE CONTROL, FLOOD CONTROL.

RIVER ICE, ICE BREAKUP, ICE JAMS, RIVER FLOW, ICE CONTROL, FLOOD CONTROL.

The entire range of ice breakup behavior, from thermal to dynamic, described and classified, to provide order to this complex process. The theory and model of Ferrick et al. (1986) are refined, building on the concept of an intrinsic relationship between river waves and dynamic ice breakup. A force balance is developed for a common dynamic breakup behavior. Empirical enteria that quantify the resistance to breakup of an ice cover are obtained from a case study and compared with published values. Sensitivity studies of ice breakup with the completed model demonstrate insights that follow from the theory presented, and the intuitive nature of the results. This framework for understanding river ice processes provides the option for ice management by river regulation, and focuses on the potential for control of ice breakup. The concept of controlled breakup involves a release of water from a dam that moves the ice downstream of locations with a high potential for damages during breakup. The abrupt, short-duration characteristics of the controlled release, patterned after those of unregulated river breakup, minimize both the volume of water required to cause breakup and the water levels at breakup. The open water created by the breakup collects heat that increases the rate of melting of the ice. The benefits of succ. ssful regulation include the prevention of flooding, min mum e osion and decreased potential for ice damage to structure, during breakup without adverse affects on the environment.

TOWERS, ICING, ICE REMOVAL, LOW FRE-QUENCIES, VIBRATION

Laboratory and field experiments showed that structurally safe levels of lcw-frequency, high-amplitude (LFHA) vibrations imparted directly to transmission tower under cold temperatures were ineffective in removing app eciable amounts of atmospheric ice. In general, limited ice removal from the test structures occurred only during resonant-mode frequencies when vibration amplitudes were greatest. More importantly, the same vibrations that were incapable of ice removal were structurally damaging to the 18-m-tall guyed towers. Damage resulted in the form of broken welds and crossbracing and cracked tower legs. Experiments with a surface coating showed that while the bond strength of the ice was reduced, debonding and ice removal was still limited to small areas close to the vibration source. Vibrations preceded by melting at the ice/metal interface and weakening of the ice cover by solar radiation led to rapid and extensive ice removal. The possibility of descing by a combination of ribrations, heat, and/or surface coatings is worthy of additional investigation.

FLUID FLOW, MATHEMATICAL MODELS
Generation of boundary-fitted orthogonal coordinates is accomplished by mapping the irregular region in physical space onto a square in the transformed space, where an elliptic equation is solved to find interior physical coordinate locations it is usual practice to employ rules or restrictions on the distortion function governing the coordinate transformation from physical to transformed space. This can allow control of node spacing on the interior of the region, at the expense of arbitrary specification of node locations along the boundaries. In problems involving internal flows, the specification of boundary node locations is important. This paper investigates some implications of a standard rule used for specification of the distortion function, and explores a simple technique of the distortion function, and explores a simple technique that achieves complete boundary correspondence by allowing natural values of the distortion function to exist on the interior. Sample grids are generated to compare the results of the two techniques.

The U.S. Army Cold Regions Research and Engineering Laboratory has a new controlled environment test facility, the Frost Effects Research Facility (FERF), now in use. The 29,000 sq. f (2942 sq. m) building comprises a principal test area 182 ft (55 m) long by 4 ft (14 m) wide incorporating 12 test basins, adjacent mobiliration areas and equipment rooms, for a total width of 102 ft (31 m), plus fully enclosed ramp areas at each end of the building. Surface panels are used to freeze pasement and soils for the pasement, utility, soil sensor, and mobility test programs. Liquid-to-air heat exchangers are used to test hardware inside enclosures erected in the test basins or on the mobilization area. Currently, coolant is available at -35 deg. 0 deg and +90 deg F (38, -18 and 38 C), allowing test temperatures ranging from -35 F (-37 C) = +90 F (32 C). Lower temperatures can be achieved by using portable units in conjunction with the facility's permanent system

YSIS (MATHEMATICS).

A new unit operation called a sludge freezing bed i, proposed for dewatering sludges produced by treatment facilities in cold regions. This unit operation uses natural freezentaw to condition the sludge for dewatering. It can dewater all types of aqueous sludges up to a depth of 2.0 m. Basic construction details are identified, and procedures for operating the bed are discussed. Equations for predicting the design depth are presented along with an example of how they can be used. Convection was found to be the controlling heat transfer mechanism during freezing. Solar radiation, ambient air temperature, and the thermal conductivity of the settled sludge layer over the frozen sludge are important parameters controlling the thawing rate. Data from various sludge freezing operations indicate that the design equations are valid.

LUTION.

A 2963 cu m residence for transient military personnei at Fort Richardson, AK, was subjected to a passive perfluorocarbon tracer gas measurement of air exchange for 3 days. The building was treated as having three separate zones corresponding to the three floors. Each zone received constant tracer gas, emission sources of the same type of gas unique to that zone. The concentrations of each tracer gas were measured throughout the building. As a consequence, it was possible to calculate the average air exchange of each zone with each other zone and the outdoors. The measurement took place during a period when the average emperature of -19 C varied approximately, 5 C up or dee in The first and second floors had air exchange rates of . 21 and 0.22 ach (air changes per hour), respectively, which as the basement had 0.70 ach. The higher exchange rate for the basement was attributed to the configuration of the

main entry doo.s and interior doors, which allowed cold air to descend to the basement, but discouraged mixing on the first flo. The measurement was significant because it represents the upper end of building su. and complexity that lends itself to this measurement technique. Measurement precision was good. The accuracy depended on adequate mixing and on minimum variation of wind and outdoor temperature. Both objectives were met reasonably

AIR MOVEMENT IN SNOW DUE TO WIND-PUMPING. Colbeck, S.C. 1989, 35(120), p.209-213, 12 refs

SNOW AIR INTERFACE, SNOW THERMAL PROPERTIES, ANALYSIS (MATHEMATICS), AIR FLOW, ATMOSPHE AIC PRESSURE, WIND FACTORS, SNOW SURFACE

Strong winds can disrupt the thermal regime in seasonal snow because of the variation in surface pressure associated with surface features like dunes and ripples. Topographical features of shorter wavelengths produce stronger surface Pows.

but the flow decays rapidly with depth features produce weaker surface flows but the flow decays more s'owly with depth. The flow may only be strong enough to disrupt the temperature field for features of wavelengths on the scale of meters or tens of meters at wind speeds of 10 m/s or more. Other possible causes of windpumping have been examined but they do not appear to be as significant. Rapid pressure perturbations due to turbulence produce very little displacement of the air because of the high frequency and low amplitude. Barometric pressure changes cause compression and expansion of the air in the pore space, but the rate is too low to have much effect.

MENT.

The inorthern temperate climatic zones experience a varying scenario of winter environmental extremes of cold, iong, and precipitation, which severely influence geople, equipment and operations. Even instruments used to measure cold and/or wet adverse environments may be incapable of operation if employed during severe cold weather. It is, important to know the equipment's environmental restrictions and to evaluate the frequency and duration of disabling weather. In some instances, functional impairments persist after the causative meteorological conditions have subsided, e.g. glaze, rime and heavy snow and tee accumulation. For c.er. 25 years, CRREL has studied environmental conditions in winter weather. These efforts have concentrated on providing field-measured meteorological data and historical climato-ogical data, as well as instrumentation support for many ogeci data, as well as instrumentation support for many experiments conducted throughout cold regions of the North-ten Hemisphere These efforts have involved characterizing atmospheric conditions as well as surface conditions. Some of the measurements made are snow temperature profiles, depth of the snow on the ground with varying terrain and vegetation, temperature at the snow/ground interface, nearsurface ground temperature and wind profiles, snow cover properties, solar radiation, visibility and sky conditions

UNCONVENTIONAL POWER SOURCES FOR ICE CONTROL AT LOCKS AND DAMS. Nakato, T, et al, Sep. 1989, 3(3), p.107-126, 15 refs. Ettema, R., Ashton, G.D.

44-1771 DAMS, LOCKS (WATERWAYS), ICE CONTROL, ELECTRIC POWER, ICE PREVENTION, ICE RE-MOVAL. ICE GROWTH, ANALYSIS (MATH-EMATICS!

Assessed by a are if e feasibilities of using several unconventional power sources for the control in navigation locks and dams included in this assessment are sensible heat from groundwater, solar power, wind power and portable hydroelectric-power sources. Operation of lock and dam installations is made troublesome and risky by the growth along lock walls and by freezing of gates to the growth along lock walls and by freezing of gates to the covers. Considerable amounts of ower are required for force the control, and therefore, loc inspirators are interested in utilizing economical alternative privar sources other than that generated by commercial power unities. However, the present study concludes that of all unconventional power sources, portable hydroelectric-power is the most viable. Groundwater is at best of marginal viability, and solar and wind power sources are unreliable.

44-1877
SNOW ACOUSTICS, SOUND TRANSMISSION, SOUND WAVES, ANALYSIS (MATHEMATICS). SOUND WAVES, ANALYSIS (MATHEMATICS).

Theoretical predictions are made of the effect of an absorbing ground surface on acoustic impulsive waveforms propagating in a homogeneous atmosphere for frequencies below 500 Hz The lower frequencies of the pulse are enhanced as the effective flow resistivity of the ground surface decreases and as the propagation distance increases. The pulse waveforms and peak amplitude decay observed for propagation distances of 40 to 27: m over grassiand were satisfactorily matched by calculations using an assumed effective flow resistivity of 200 kN/s/ 0001 m Measurements over snow gave much greater amplitude decay fates, and the waveforms resistivity of 200 kN/s/ 0001 m Measurements over snow gave much greater amplitude dees; rates, and the waveforms were radically changed in appearance, being dominated by the lower frequencies

These waveforms were satisfactorily matched only when a layered ground was incorporated into the calculations; then, ar assumed surface effective flow resistivity of 20 kN/s/ 0001 m gave good agreement with the observed waveforms and peak amplitude decay

CAL FACTORS.

This paper discusses a study that was undertaken to discriminate between four icephobic coatings for ease of ice removal. The method of discrimination was to compare the shear force required to remove a buildup of freshwater ice from flat plate test surfaces measuring 22 9 x 38 1 cm. Twelve replicates each of the four different coatings and two different control surfaces (a total of 72 samples) were subjected to spray icing in an environmental chamber. The sam, les were iced and shear tested at -10 C. The tests were performed using a constant displacement rate of 0 0381; km/s. This shear rate ensured a brittle failure at the ice/coating interface and produced virtually 100%, ice removal in every This shear rate ensured a brittle failure at the ice/coating interface and produced virtually 100% ice removal in every rest. Results showed that all four of the experimental patings exhibited higher mean shear values than either of the two controls. Although the mean shear values for the various coatings were very similar in absolute magnitude ranging from 71 to 119 kPa, statistical analysis showed that their was a significant difference in coating performance with greater than 56% confidence. The relative standard deviation in shear values ranged from 15 to 29% of the total stre. The distinction is emphasized between decing and anti-ieing surfaces relative to coating performance and anti-ieing surfaces relative to coating performance. and anti-icing surfaces relative to coating performance

DYNAMIC ANALYSIS OF A FLOATING ICE SHEET UNDERGOING VERTICAL INDENTA-

Michibary, W.K., et al. International Conference on Offshore Mechanics and Arctic Engineering, 9th. Houston, TX, Feb. 18-23, 1990. Proceedings Vol. 4. Edited by O.A. Ayorinde, N.K. Sinha and D.S. ICE MECHANICS, FLOATING ICE, DYNAMIC PROPERTIES, LOADS (FORCES), ICE DEFORMATION, BEARING STRENGTH, OFF THORE STRUCTURES, VELOCITY, MODELS SHORE DRILLING, ICE ROADS, TESTS

This paper describes a finite-element model of a floating ice sheet subjected to rapid vertical indentation. We modeled the ce sheet using small-ineflection, clastic-plate theory and modeled the fluid using incompressible potential flow.

The objectives were to assess the validity of this coupled model to predict indentor loads and to determine the relative importance of fluid inertia versus ice-sheet inertia. The model's talidity is assessed by comparing its predictions with previously obtained laboratory data. It is found that the model yields reasonably good predictions of indento loads and sheet diffection profiles provided the ice sheet's characteristic length is reduced to account for damage caused by large deflection. The model also clearly demonstrates the predominance of fluid inertia over ice-sheet inertia for the case of rapid vertical indentation. Indeed, it was found that the ice sheet essentially behaves as a massless, clastic plate on a fluid foundation.

Cote, D.M., international Conference on Oilshore Mechanics and Arctic Engineering, 9th, Houston, TX. Feb 18-23, 1990 Proceedings Vol.4 Edited by O.A. Ayorinde, N.K. Sinha and D.S. Sodhi, New York, American Society of Mechanical Engineers, 1990, p. 265-271, 10 refs.

ICE LOADS, ICE SALINITY, STRESS STRAIN DIAGRAMS, LOADS (FORCES), COMPRESSIVE PROPERTIES, ICE ELASTICITY, TENSILE PROPERTIES, MEASURING INSTRUMENTS. EXPERIMENTATION, ICE CORES, TEMPERA-TURE EFFECTS.

This paper describes the initial experimental results on the cyclic loading of saline ice specimens obtained under fully reversed (tension-compression) uniaxial loading conditions. The apparatus used to grip the 100-m-dia..., seemens is similar to one described in Cole and Gr. 3d (1989) for performing reversed direct stress tests on 50-m-diameter speciperforming reversed direct stress tests on 50-m-diameter specimens. Results were obtained for sinusoidally sarying axia stresses ranging from 0.3 to 0.9 MP and for loading frequencies in the range of 00025 to 10 Hz. The test temperatures were -10 a.1 -20 C. The specimens were saline ice cores taken from an outdoor facility at CRREL. The tee exhibited varying degrees of inelastic behavior under all conditions experienced in these experiments the initial cycle of loading at frequencies in the renge of 0.1 to 10 Hz resulted in closed hysteresis loops, while lower frequencies produced open loops. The net strain at the end of the open hysteresis loops was virtually all recovered within a short time after the end of a single loading cycle for the 100s period was closers. However, for the loading periods of 1000 and 4000s the bulk of the strain required to close the hysteresis loop. Aas generally not recoverable. The the hysteresis loop Aas generally not recoverable. The loading sequences were such that all specimens ultimately failed in tension with the fracture occurring in the deformation. measurement gauge length

MP 2582 DETERMINATION OF THE UNDERSATURA-TION IN THAWED PERMAFROST AT THE BE-GINNING OF FREEZEBACK.

Avorinde, O.A. International Conference on Offshore Ayorinde, O.A., International Conference on Offshore Mechanics and Arctic Engineering, 9th, Houston, TX, Feb. 18-23, 1990. Proceedings Vol.4. Edited by O.A. Ayorinde, N.K. Sinha and D.S. Sodhi, New York, American Society of Mechanical Engineers, 1990, p.317-321, 3 refs. 44-2241

PERMAFROST, FREEZE THAW CYCLES, DRILLING, SATURATION, POROSITY, GAS WELLS, OIL WELLS, MATHEMATICAL MODELS, WELL CASINGS, SOIL COMPACTION, UNFROZEN WATER CONTENT.

FROZEN WATER CONTENT.

In permafrost, the initial undisturbed degree of saturation can be significantly reduced when subjected to several cycles of thaw-subsidence and freezeback usually encountered during oil/gas well drilling and production operations. The changes in saturation and the resulting u dersaturation should be considered in the analysis and modelling of permafrost properties. Consideration of the reduction in saturation is lacking in most of the published freezeback and thaw-subsidence models. A mathematical relation is derived to evaluate the undersaturation in the permafrost at the beginning of each freezeback process during several thaw-subsidence-freezeback cycles. The undersaturation is related to the initial unifrozen water content and the permafrost compaction caused by thaw-subsidence. The mathematical analysis shows how the effects of the initial unifozen water content and the by thaw-subsidence. The mathematical analysis shows how the effects of the initial unifozen water content and the permafrost compaction due to subsidence can be taken into account in determining the freezeback pressures. A relationship for the initial gas fraction is also developed which can be incorporated in the freezeback model Furthermore, upper limits are established for the permafrost compaction or thaw consolidation (volumetric strain) for various possible conditions that may be encountered

These passive heat transfer devices have been used under buildings, roads, railroads, pipelines and airfields. Laboratory lests were conducted on a full-size commercial, two-phase thermosyphon in CRREL's atmospheric wind tunnel. The unit was tested at evaporator angles of 9, 7, 3, and 0 degree and condenser angles of 90, 45 and 9 degrees from the horizontal. The condenser section, was subjected to wind speeds range. angues of 90, 40 and 9 degrees from the horizontal. The condenser section was subjected to wind speeds ranging from 0 to 7 m/s. Performance of the thermosyphon as a function of these variables is presented. The component thermal resistances of an in-place thermosyphon were calculated. It was determined that the thermal resistances associated with conduction through the soil and heat transfer from the fins to the air are dominant

HAMPSHIRE—MOUNT WASHINGTON.

Atmospheric rime icing, resulting primarily from supercooled cloud droplet impaction on objects at the Earth's surface, was monitored and analyzed as a function of clevation on the west faces of Madonna Peak and Mount Mansfield in the Green Mountains, Vermont, and at the summit of Mount Washington, New Hampshire. Measurements were made of ice accretion rates on passive, manually operated collection baskets and automatic ice detectors. Leing rates pressure accordingly with elevation shows about 800 and 100 an made of ice accretion rates on passive, manually operated collection baskets and automatic ice detectors. Icing rates increase exponentially with elevation above about 800 m, with secondary controls of rate suggested by microtopographic relief exposure. The illustrated dependence of icing rate upon elevation is largely a function of New England wind and cloud regimes and differs from other selected mountainous locations. The relationships presented may help assess the magnitude of frozen moisture inputs to high-elevation mountain executions. mountain ecosystems

INTRODUCTION TO DRILLING TECHNOLO-

Mellor, M., International Workshop on Physics and Mechanics of Cometary Materials, Münster, FRG, Oct. 9-11, 1989 Proceedings, European Space Agency, Dec. 1989, p.95-114, ESA SP-302 44-2800

DRILLING, FROZEN GROUND, ICE CORING DRILLS, EXTRATERRESTRIAL ICE, PLANE-TARY ATMOSPHERES

Terrestrial drilling technology is reviewed. The general requirements for a drilling system are given and conventional drilling techniques (rotary drag bit, rotary roller bit, percussive, rotary-percussive) are described. Unconventional techniques for penetrating solids are outlined, including thermal drilling (spalling or melting), projectile penetration, high

pressure liquid jets, explosive jets, erosion by projectile streams, and chemical penetration Special attention is given to drilling in ice and frozen soils, performance data are given, including values for penetration rate and specific energy consumption The principles, theory and equipment relating to each drilling technique are indicated by means of diagrams

POLLUTION, CHEMICALS.

Ion-pairing reversed phase-high performance liquid chromatography methods were developed to determine tetrazene in water and soil. Determinations were achieved using an LC-18 column, a mobile phase of 2/3 //v methanol-water containing 0.01 M 1-decane-sulfonic acid sodium salt, and a UV detector set at 280 nm. The pH of the mobile phase was adjusted to 3 with glacial acetic acid, which was optimal for separation of tetrazene from potential interferences by other explosives. The retention time for tetrazene was 2.8 minutes. A linear model with zero intercept was found to adequately describe the calibration data for concentration ranges of 6.1 to 122 micrograms/L for water samples and 0.204 to 4.08 micrograms/g for soil samples Tetrazene was found to be unstable in an aqueous medium at room temperature. Concentrations decreased by 96-100% over 24 hours. The rate of degradation was reduced significantly when solutions were maintained near 0 deg C.

Freezing and thawing of soil systems are usually formulated and discussed in terms of plane or Cartesian coordinate systems. Thus most freeze/thaw equations are based on the Neumann solution. However, many practical soil phase change problems, such as freezing around butted pipes, deal with cylindrical coordinates. The basic equations, solution methods, and solutions for freezing and thawing in cylindrical coordinates are presented here along with some graphs for resection. practical applications

PHYSICAL CHANGES IN CLAYS DUE TO FROST ACTION AND THEIR EFFECT ON ENGINEERING STRUCTURES.

SOLIDATION.

Freezing and thawing cause changes in the physical and engineering properties of clay soils. The properties of clay soils are particularly susceptible to frost action because the structure and fabric are very sensitive to the stresses that are caused by freezing. This report presents a review of the state of understanding of how changes in the soil fabric and structure occur and how these changes affect the engineering properties of clays and ground freezing projects.

MODELING ICE RESTRAINT FORCES IN AN ICE BOOM.

Perham, R E, IAHR Symposium on Ice, 9th, Sapporo, Japan, Aug. 23-27, 1988. Proceedings, Vol.3, Japan, Aug. 23-27, 19 [1988], p.198-206, 3 refs. 43-3033

BOOMS, ICE PRESSURE, BUOYANCY, DELS, MATHEMATICAL MODELS, COM-MODELS PUTER PROGRAMS

PUTER PROGRAMS

A model of the ice restraint forces in a floating ice boom having rectangular cross-sectional boom units has been developed. By knowing the boom unit dimensions, buoyancy, and anchor characteristics, one can predict the boom's ability to restrain ice up to certain force levels. In operation, a boom unit tends to be upset by the force coupling that develops between ice forces and structure forces that generally are not collinear, the rectangular unit resists being overturned by virtue of its righting moment that increases with tilt, up to a limit The model is very important now that alternative materials to replace Douglas fir in the boom unit show more economic and technical promise. For the first time an ice boom can be designed and engineered in a fully comprehensive manner. Ice restraint forces and righting moments are given in dimensionless terms, Frand M*, respectively, as Fr*=M*2p/G where p and G relate to the geometry of interaction between the boom unit, the ice and the structure Laboratory tests show that the model yields conservative values of ice restraint capacity, ie minimums for a prototype.

43-3211 SOIL STRUCTURE, FROZEN GROUND PHY-SICS, SEASONAL VARIATIONS, SNOW ACOUSTICS, FREEZE THAW CYCLES

TICS, FREEZE THAW CYCLES
Results are presented from a field program conducted in 1985/86 to investigate the changes in acoustically coupled ground motion due to the presence of snow and/or frozen ground. The acoustic source was blank pistol fire. The addition of a 6-cm-deep layer of snow to bare ground causes a greater reduction in the amplitude of coupled ground motion than does tripling the snow depth from 6 cm to 18 cm. The amplitude of coupled ground motion is 80-90% lower in hard frozen sand (sand frozen when saturated) than it is not try inforcer sand (sand frozen when saturated). than it is in dry unfrozen sand.

COMPARATIVE STUDIES OF THE WINTER CLIMATE AT SELECTED LOCATIONS IN EUROPE AND THE UNITED STATES.

Bates, R.E., et al, Annual EOSAEL/TWI Conference, 9th, Nov 29-Dec 1, 1988 Proceedings, Vol. 1, Mar. 1989, p.283-293, 17 refs.

CONVECTION, HEAT TRANSFER, ICE SHEETS, ICE MELTING, ICE WATER INTERFACE

CONVECTION, HEAT TRANSFER, ICE SHEETS, ICE MELTING, ICE WATER INTERFACE.

Experiments were conducted to study the melting of a horizontal ice sheet with a flow of water above it. The experiments were conducted in a refrigerated flume 35 m long with a cross section of 1.2 x 12 m. Water depth, temperature and velocity were varied as well as the temperature and initial surface profile of the ice sheet. It was found that the heat transfer regimes consisted of forced turbulent flow at high Reynolds numbers with a transition to free convection heat transfer at lower Reynolds numbers. There was no convincing evidence of a forced laminar regime. The data were correlated for each of the regimes with the Reynolds number, or Gr/Re25, used to characterize the different kinds of heat transfer. For very low water velocities over a hortizontal ice sheet, the melting heat flux does not drop below the value for the free convection case as long as the water temperature exceeds 34 C. This is significant since the free convection. At the low velocities the melting flux was not dependent upon the fluid temperature until the water temperature dropped below 3.4 C. The heat transfer was found to significantly exceed that of non-melting systems for the same flow regimes This was attributed to increased free stream trubulence, thermal instability due to the density maximum of water near 4 C, and the turbulent eddies associated with the generation of a wavy ice surface during the melting

MP 2601 SOME PECULIARITIES OF CREEP BEHAVIOR OF FROZEN SILT.

Fish, A.M., International Conference on Offshore Mechanics and Arctic Engineering, 8th, The Hague, Netherlands, Mar. 19-23, 1989. Proceedings. Vol.1, New York, American Society of Mechanical Engineers, 1989, p 721-724, 9 refs.

FROZEN GROUND MECHANICS, FROZEN GROUND STRENGTH, SOIL CREEP, RHEOLO-

GROUND STRENGTH, SOIL CREEP, RHEOLO-GY.

A study has been conducted on creep of frozen Fairbanks silt at a constant temperature of -2 C. The entire creep process (primary, secondary and tertiary) is described by means of two rheological characteristics the time parameter lambda and the viscous failure strain C (the product of the minimum strain rate em and the time of failure tim). A new method is presented for determining these parameters and the time to failure from a single linear plot in which each individual creep curve forms a straight line for both primary and tertiary creep. Secondary creep is considered to be a principal point on this line that predetermines the onset of failure. The two parameters of the straight line (the intersection with the ordinate and the slope) define the magnitudes of the creep parameters. It was found that the shapes of the creep curves, and thus the creep parameters of frozen soil, strongly depend upon sitess. Although theoretically the time parameter lambda can change from 0 to 1, only variations of lambda between 0.6 and 0.8 can be observed in short-term creep tests. It is also shown that parameter C does not retain a constant value. The absolute value of C varies between 3 and 9%, and its variations with sitress correspond to Maxwell's distribution. The sitess dependencies of the creep parameters developed in this paper make it possible to extrapolate the values obtained in short-term tests at high stresses for long-term creep at small sitesses. It is shown that the errors in creep strain calculations may be up to an order of magnitude if stress variations of creep parameters are ignored. are ignored.

SEA ICE, CLOUDS (METEOROLOGY), ICE OPENINGS, BACKSCATTERING.

OPENINGS, BACKSCATTERING.

Remote sensing using an airborne infrared lidar has shown an unexpected capability to detect open leads (linear openings) in Arctice sea ice and their associated meteorology in winter Here we show that sertical profiles of backscattered radiation demonstrate strong returns from hydrometeor plumes originating from leads having a surface water temperature near 1.8 C. Recently refrozen leads are also distinguishable by the lidar backscatter from adjacent thicker, older sea ice. Wide leads release enough energy to create buoyant plumes which penetrate the Arctic boundary layer inversion, transporting heat and moisture into the troposphere. These results show that the role of the Arctic as a global heat results show that the role of the Arctic as a global heat sink may need to be re-evaluated, and that lead plumes have a significant effect on the radiation budget

TWO-STREAM APPROXIMATION TO RADIA-TIVE TRANSFER IN FALLING SNOW

Koh, G., Smoke/Obscurants Symposium, 12th, Laurel, MD, Apr. 19-21, 1988. Proceedings. Vol.2. Unclassified section. Edited by W.M. Farmer and W. Klimek, July 1988, p.463-470, 7 refs.

BACKSCATTERING, LIGHT TRANSMISSION, SNOW OPTICS, SNOWFALL.

Light transmission measurements through falling snow have produced results that cannot be explained by single scattering arguments. A two-stream approximation to radiative transfer is used to derive an analytical expression that describes ter is used to derive an analytical expression that describes the effects of multiple scattering as a function of the snow optical depth and the snow asymmetry parameter. The simple approximate solution is compared with the experimental results. It is shown that the approximate solution may be as accurate as the exact solution for describing snow transmission measurements within the limits of the experimental uncertainties.

LIGHT TRANSMISSION, SNOWFALL, CLOUD CHAMBERS, SNOW OPTICS, TIME FACTOR.

CHAMBERS, SNOW OPTICS, TIME FACTOR.
Recent experimental and theoretical work has shown that falling snow can remove appreciable amounts of aerosols from obscurant clouds. Field measurements of scavenging efficiencies for brass infrared screener averaged 30% for various snow crystal types. Although increases in transmission and visibility resulting from snow scavenging of particles have been calculated and modeled, quantitative transmission measurements have not previously been conducted. In order to perform such transmission measurements, ad dynamic obscurant cloud chamber was constructed, through which an upward flow of controlled concentrations of brass screener was maintained. The chamber work was opened to permit falling snowflakes to scavenge particles from the upward-moving obscurant cloud. A 633-mm He-Ne laser transmission-through the chamber over a 1-m path leight at two heights. 15 m apart. The difference in transmittance between the two levels is a measure of the amount of obcurant removed. This experimental arrangement is able to measure the rate of scavenging upon electro-optical (E/O) transmission for precipitation rates as light as 0.08 g/sq ms (0.18 mm hrater equivalent). Results venify earlier predictions of reduced effectiveness of infrared screeners during precipitation Field tests conducted during 1987-88 winter snowstorms using brass screener indicate that smoke particle scavenging can cause relative transmission increases of as much as 5-15% for each minute of exposure to snowfall. can cause relative transmission increases of as much as 5-15% for each minute of exposure to snowfall

THEORIES, LIGHT TRANSMISSION, SNOW-FALL, SNOW OPTICS, SNOWFLAKES.

FALL, SNOW OF ITCS, SNOWPLAKES.
Falling snow has been observed to collect screener materials with relatively good efficiency. This paper describes a semiempirical theory that predicts the rate at which falling snow diminishes screener concentration. The theory incorporates snowflake size distributions, suspended snow concentration. porates snowlake size distributions, suspended snow concentration, snowfall rate, optical transmission and meteorological parameters from the SNOW experiments. These parameters are used, along with fall velocities from the work of O'Biren, Locatelli and Hobbs, and Mellor, to calculate the volume of air swept by falling snow, as a function of precipitation rate. Calculations are performed using this theory to predict screener scavenging rates, these indicate that very light snow falls are capable of halving smoke concentrations in hundreds of seconds.

IMPACT OF WET SNOW ON VISIBLE, INFRA-RED AND MILLIMETER WAVE ATTENUA-TION.

Bates, R.E., et al, Smoke/Obscurants Symposium, 12th, Laurel, MD, Apr. 19-21, 1988. Proceedings. Vol.2. Unclassified section. Edited by W.M. Farmer and W. Klimek, July 1988, p.523-535, 10 refs. 43.3439

WET SNOW, SNOWFALL, TRANSMISSION, WAVE PROPAGATION, SNOW CRYSTAL STRUCTURE, PRECIPITATION (METEOROLO-

Examination of visible, infrared, and millimeter wave attenuation by falling snow during the coastal snowstorm of Dec 13-14, 1985 at Ft Hollis, ME, (SNOW IV) indicates a peculiarity in transmission that may have resulted from a snow/rain phase change. During this period the type of precipitation changed, while the surface temperatures and the low-level vertical temperature profile fluctuated around O.C. Analyses of the transmission data over a portion of the snowstorm indicate that the infrared and visible attenuations were less than the millimeter-wave attenuation. These results from SNOW IV are compared with those from moderate to heavy wet snowfalls during previous SNOW expe., ments, Previous results indicate that millimeter-wave radiation is normally attenuated less than visible or infrared radiation by moderate to heavy snowfall. Meteorological data and observations of snow crystal habit in similar storms that occurred during all of the SNOW experiments are analyzed to examine transmission Procepitation-phase-change relationon of visible, infrared, and millimeter wave att to examine transmission/precipitation-phase-change relation-

MP 2609 OVERVIEW OF OBSCURATION IN THE COLD ENVIRONMENT.

TION, MELTWATER.

Roofs continue to be a problem in cold regions even though many excellent membrane and water-shedding systems are available. Dead flat roofs of any type are a design mistake In cold regions, membrane roofs should have a slope of 1/4 in./ft and should drain internally It is usually best to slope roofs by inclining the frame rather than using tapered insulation. Most water-shedding roofs drain to cold eaves and are thus subject to ice dam problems. Such problems can be minimized by designing a "cold" ventilated roof, by insulating it well, by minimizing the overhang at the caves, by increasing the roof slope and by providing an unobstructed slippery surface from which snow will slide However, when using slippery-surfaced systems, it is essential to provide a place for the snow to slide where it will not endanger people or damage property.

SEA ICE, FRAZIL ICE, ICE FORMATION, ICE GROWTH, ANTARCTICA—WEDDELL SEA.

GROWTH, ANTARCTICA—WEDDELL SEA.
Development and physical properties of sea ice in the central and eastern Weddell Sea are reported. Major elements of the glaciological part of this study include continuous shipborne observations of sea-ice conditions and occasional helicopter reconnaissance flights, extensive measurements of snow and ice thicknesses at daily ice stations, and detailed analyses of sampled ice corest from each ice station. Textural investigations of the sampled ice revealed the dominance of fazil ice in the central Weddell Sea and the occurrence of an additional ice class, called platicle ice, together with the commonly known frazil and congelation ice in the coastal region of the castern Weddell Sea. These results, in combination with the visual ice observations, reveal two major mechanisms for sea-ice generation in the Antarctic, which were not sufficiently well accounted for in previous investigations. In the central Weddell Sea, a cycle of pancake-ice formation and its growth into consolidated floes seems to be the dominant process of the advancing sea-ice edge. In the coastal and its growth into consolidated floes seems to be the dominant process of the advancing sea-ice edge. In the coastal waters, the growing sea-ice cover consists, to a considerable degree, of ice platelets which are formed in the underlying water column in front of the ice-shelf edges. Thus, congelation-ice growth, which is mainly controlled by atmospheric, thermodynamic forcing, seems to be of less importance in the central and southeastern Weddell Sea than, for example, in the Arctic Basin (Auth)

DEWATERABILITY OF FREEZE-THAW CON-

DITIONAL SLUDGES.
Martel, C.J., Feb. 1989, 61(2), p.237-241, 26 refs.

SLUDGES, SEWAGE TREATMENT. FREEZE DRYING, FREEZE THAW TESTS

DRYING, FREEZE THAW TESTS

In this study the limiting depth of freeze thaw conditioned sludges was determined. Column tests were conducted at four depths ranging from 30 to 220 cm. A water treatment sludge, an anaerobically digested wastewater sludge were tested. Results indicated that up to 20 m of each sludge would drain within minutes after freeze-thaw conditioning. After drainage, the average solids content in the water treatment and anaerobically digested wastewater sludges was high enough for mechanical removal. In comparison the uniforen sludges were still draining after 2 weeks. Application of the freeze-thaw conditioning process would best be accomplished in a new unit operation called a sludge freezing bed.

FROZEN GROUND STRENGTH, FROZEN GROUND COMPRESSION, STRESS STRAIN DIAGRAMS, SOIL SURVEYS.

DIAUKAMS, SOIL SURVEYS.

At the request of the Ballistic Missale Office, the US Army Engineer Waterways Experiment Station conducted surficial soil studies at four locations in the Malmstrom sitting area in Montana. The purpose of this work was to support whicle stability analyses asso-rated with nuclear environment definitions for the Air Force's proposed Hard Mobile Launcher basing mode for a Small Intercontinental Ballistic Missale. This report documents the results of a study conducted basing mode for a Small Intercontinental Ballistic Missile. This report documents the results of a study conducted by personnel of the US Army Cold Regions Research and Engineering Laboratory to characterize the frozen strengths of the soils encountered at four off-road sites. Presented are the results of static laboratory trianial compression tests conducted chiefly on frozen undisturbed samples obtained from the upper 20 inches of each site. Multiple linear regression analyses of these data were conducted to identify relationships between the soil strength at each site and moisture content, density, temperature, and confining pressure.

SEA ICE, FRAZIL ICE, ICE ELASTICITY, AN-TARCTICA--WEDDELL SEA.

TARCTICA-WEDDELL SEA.
We present data on the elastic properties of antarctic sea ice from the Weddell Sea area. The data have been obtained through measurements of compressional- and shearwave velocities on frazil ice at ultrasonic frequencies (1 MHz). Sample (total) porosities range from 2 to 97- and salimities from 2.3 to 71 ppt. The measured compressional- and shear-wave velocities lie at 36 to 38 km and at 14 to 19 km s, respectively. The thear-wave velocities of the present samples he significantly below those obtained under similar experimental conditions for Arctic frazil ice. The resulting elastic constants range between 5 to 9GPa 7.5 to 10GPA, 1.5 to 32GPa and 0.32 to 0.42 for Young's modulus, bulk mediulus, shear mediulus and Poisson ratio, respectively louised in compression tests on the same samples, are in good agreement with or slightly above the dynamic Young's modulu.

FRAZIL ICE, SEA ICE, ICE PRESSURE, ICE DEFORMATION, ICE STRENGTH, STRAIN TESTS, ANTARCTICA—WEDDELL SEA.

TESTS, ANTARCTICA—WEDDELL SEA.

Unconfined, untaxial compression tests were performed on frazil sea ace samples collected in the Weddell Sea, Antarctica. The tests were done at a constant strain rate of 0001/s and at temperatures of -3, -5 and -10 C. Data from the frazil are tests were compared to results from tests done under the same conditions on transversely isotropic, columnar saline ice. The approximate grain sizes of the frazil and columnar tee were 1 and 10 mm, respectively. The results of this work indicate that the frazil ice generally has a higher strength than columnar ice loaded in the place of the sheet. Tests done by other researchers on freshwater, equiaxed polycrystalline ice have also shown the compressive strength to vary inversely with grain size. Application of this relationship to the sea ice tests at a strain rate of 0001/s cannot be directly extended to explain the variation in compressive strength between the frazil and columnar sea ice. We speculate that this may be due to either (1) the influence that the increased ductility of sea ice has on the relationship between strength and grain size at 0001/s. (2) that another microstructural parameter (e.g. the thickness of the ice between brine inclusions) may be the controlling factor in determining sea ice strength, or (3) that the dominant mechanisms driving deformation vary with each ice type. (Auth.)

MP 2622 MODEL TESTS ON AN ICEBREAKER AT TWO FRICTION FACTORS

Tatinclaux, J.C., International Conference on Port and Ocean Engineering under Arctic Conditions, 10th, Luleå, Sweden, June 12-16, 1989. Proceedings. POAC 89. Vol.2. Edited by K.B.E. Axelsson and L.A. Fransson, Luleå, Sweden, University of Tech-nology, 1989, p.774-784, 7 refs. 43-3776

METAL ICE FRICTION, ICE SOLID INTER-FACE, MODELS, ICE STRENGTH, PROPEL-LERS, ICE THICKNESS.

Results of resistance and propulsion tests in level ice of a model of the Canadian R-class icebreaker for two values of the ice-hull fretion factor are presented. The increase in ice resistance due to increased ice friction was significant for thick, weak ice, but negligible in thin and strong ice. for thick, weak ice, but negligible in thin and strong ice.

Also, the increase in the friction factor had no detectable
effect on propeller performance. Ice-propeller interaction
had little effect on the model thrust coefficient, but a strong
one on the torque coefficient and the average thrust deduction
factor. Comparison of the test results with full-scale trial
data showed that ice-propeller interaction was more severe
at model scale than at full scale for ice thickness up to
about 0.7 m. For thicker ice, model and field data were in very good agreement.

ELECTROMAGNETIC PROSPECTIONS.
Authorne remote measurement of sea see thickness has been an elusive goal. Many sensing systems have been tried and evaluated, including impulse radar. All these systems were found to have limited capabilities at best. We are now evaluating authorne electromagnetic induction technology, which has long been used for mineral prospecting. now evaluating airborne electromagnetic induction technology, which has long been used for mineral prospecting. Two field studies have been made in the Arctic. One study has been done using a relatively standard 7-m-long, 1/2-m-diameter helicopter-towed antenna, and one using a lighter down-sized antenna only 3 m long and 1/3 m in diameter. The airborne sea ice thickness sounding profiles obtained indicated that the thickness could be estimated but the resolution decreased as the ice became rough. This decrease was associated with the large footprint of the system, which effectively smoothed out the sea ice relief. However, it was found that the average ice thickness estimated by airborne electromagnetic sounding for a given flight track was in reasonable agreement with the average ice thickness determined by direct drill hole measurement. Examples of the ice thickness profiles obtained by airborne sounding and direct drill hole sounding are presented and compared and direct drill hole sounding are presented and compared future development of the airborne system is discussed

An extensive field test was conducted during the winter of 1987 to provide data for the further development and evaluation of CRREL's snow temperature model. The programs ran continuously for two months under a variety of weather conditions. Thermal measurements and infrared imagery were made of natural snow and three sets of tank tracks. General observations from the field test are presented, along with a more detailed discussion of selected data. An improved snow temperature model will be tested against measurements from the field test.

EFFECTS.

This paper describes a Snow-Covered Terrain Thermal Model for predicting snow surface temperatures. To characterize snow-covered terrain, the model uses at most two distinct snow layers over a ground layer. The snow layers correspond to combinations of new snow, old snow, or compacted snow Based on a transmission line theory analogy, the model calculates the characteristic impedance of the snow-ground combination. Using this characteristic impedance, the model calculates the thermal response of the combination to time-varying heat input at the snow surface. The model uses standard meteorological observations to calculate the ne-least transferred across the air/snow interface. This paper also presents comparisons of modeled snow surface temperatures. The ALBE WS001 Weapon Systems Performance Tactical Decision Aid being developed by the US Army Atmospheric Sciences Laboratory will incorporate the Snow-Covered Terrain Thermal Model.

The variation of acoustically induced ground motion with the freeze/thaw state of the ground was investigated in Feb.Mar. 1986. A test chamber of the CRREL Frost Effects Research Facility containing a sand layer 0.7 m deep was outfitted with a movable roof and one movable wall. With the roof and wall in place, freezing of the sand was accomplished by blowing cold air into the chamber Arrays of thermocouples indicated the depth to which the sand had frozen. Ground motion induced by blank fire from a .22 cabber pistol was monitored with geophoses at depths of 0 to 45 cm in the sand. The results presented are for simulated winter or transitional ground conditions (The sand, either dry gambent mosture content) or saturated, was sufforces, forcer or transitioning through freezing or thawing.) Potential effects of the freeze/thaw state of the ground on the performance of seismic sensor systems are discussed.

A model is developed to describe the scavenging of smoke particles by snow. The concentration of smoke produced by rapid burst grensdes is approximated by an exponential decay and for this case the reduction in the obscuration time is derived in terms of the snow scavenging efficiency and the smoke decay rate. Measurements of the snow scavenging efficiency are used to predict the reduction in obscuration time in typical winter scenarios. Results show that snow savenging may significantly reduce the effectiveness of grenade screening smokes.

GATION, RADAR.

Comparisons of visible, infrared and millimeter wave attenuation by falling snow at SNOW IV, Hollis, Maine, indicate that as the snowstorm of Dec. 13-14, 1985 passed the site a snow crystal phase change (snow to rain) occurred. Mited precipitation types were observed during this period. As the air mass approached the Hollis, Maine, area the near-surface upper air profile and surface temperatures averaged near 0 C. Analyses of the transmission data over a poetion of the snowstorm show less infrared and visible attenuation than millimeter wave attenuation. These results are not consistent with those obtained for previous snow experiment storm analysis. I.e. normally millimeter wave radiation is consistent with those obtained for previous show experiment storm analysis, i.e. normally milimeter wave radiation is attenuated less by moderate to heavy snowfalls than visible and infrared radiation. Data and analyses are presented in this paper, comparing concurrent snow crystal habit and meteorological data (both upper air and surface conditions) with transmission measurements to examine this phase change relationship

SNOW COVER EFFECT, RADIO ECHO SOUND-INGS, MICROWAVES, BACKSCATTERING, RADAR ECHOES, SNOW COVER STRUCTURE, WET SNOW, SNOW AIR INTERFACE, SNOW SURVEYS.

A series of experiments was performed to determine radar scattering amplitude sariations in dry and wet soom. Two frequency modulated continuous wave (FMCW) radars were used in this investigation. These radars were monited

side by side on a gantry approximately 5 m above the saow field and with a depression angle of 80 degrees. The dimensions of the snow field were 30 x 15 m. The two radar systems could be scanned across the 15-m width of the snow field automatically and moved lengthwise by hand. Backscatter measurements of dry and wet snow were made to determine the variation of radar backscatter cross section as a function of liquid water content. Backscatter measurements were also made after insertion of an aluminum plate into the snow cover at various depths to determine whether there was any variation in the 35-GHz backscatter due to the reduction of volume scattering.

INDIA—YAMUNA RIVER.

Snow accumulation and ablation in the front range of the Himslaynn Mountains accounts for a considerable portion of winter and spring streamflow from the Upper Yamona River Basin. To quantify this contribution, the Central Water Commission (CWC) of India has been collecting hydrometeorological data and conducting snow surveys in the Sundli Nala Watershed, a small tributary of the Paber River that drains into the Upper Yamona River system. Hydrometeorological data from the Sundli Nala watershed, from Dec. to Mar. for the years 1944-1948, were input into the two snowmelt options of the Streamflow Synthesis and Reservoir Regulation (SSARR) model to determine the relationship of snowmelt ranoff to observed discharge. For this period, the observed streamflow data indicated that snowmelt data on contribute significantly to the overall yearly discharge. Losses due to sublimition and evapotranopiration of the remaining available meltwater infiltrates to baseflow. decrease the effect of snowmelt runoff. A large portion of the remaining available meltwater infiltrates to baseflow. This study provides for the first time a better understanding of the snowmelt dynamics in this region of the world. The data base being developed in the Sundli Nala can be used to calibrate the hydrologic forecasting model being developed by the Indian CWC to manage the water resources for the Upper Yamuna River

SNOW-CRYSTAL GROWTH WITH VARYING SURFACE TEMPERATURES AND RADIATION PENETRATION.

THEORIES, HEAT TRANSFER, THERMA CONDUCTIVITY, FREEZING, CONDUCTION.

CONDUCTIVITY, FREEZING, CONDUCTION.

Freezing of water or melting of ice are phenomena that underlie many immportant scientific and engineering studies of cold regions. Mathematical methods of treating these phase-change heat transfer problems are critical to understauding and dealing with the problems that freeze-thaw causes. This review deals only with systems for which conduction is the basic heat transfer mode or for which the solutions can be obtained in terms of conduction-like problems. While convection is an important heat transfer mode, it can often be neglected without significant error. Exact solutions are noted where available, but since these are quite limited for phase-change problems, references to approximate solutions are listed in some detail. The approximate methods are the perturbation method, which leads to quasi-stationary techniques, and heat balance integral method.

HEAT TRANSFER, WATER FLOW, ICE WATER INTERFACE, FLOW RATE, EXPERIMENTATION, ICE MELTING, THERMISTORS, AC-CURÁCY.

CURACY.

Experiments have shown that heat transfer is greater for water flowing over tee than for water flowing over flat plates without ice.

The mechanisms which contribute to this increased heat transfer are not completely understood One possible cause is the density inversion of water at 4 C. In order to investigate this effect on heat transfer, a small open-channel flume was designed so it. Aperiments could be conducted with the flume bed at temperatures slightly above 0 C with no ice present. For fully developed turbulent 3 low (Reynolds numbers greater than 20,000), heat transfer correlations initially showed higher heat transfer rates than those obtained from experiments in flume with large aspect ratios. Velocity profile corrections, to account for the aspect ratio, were applied to the data, which then agreed more closely with the results from wider flumes. The results indicate that the density inversion of water could account for most of the increased turbulent heat transfer rate observed between melting and nonmelting systems. MP 2650

CHANGES COMING IN SNOW LOAD DESIGN CRITERIA.

Tobiasson, W., Corps of Engineers Structural Engineering Conference, St. Louis, Missouri, June 27-July 1, 1988, Vol.2. Washington, D.C., Directorate of Engineering and Construction, 1989, p.918-920. 43-4410

DESIGN CRITERIA, SNOW LOADS, SNOW SLIDES.

The technical basis for the snow load design criteria used by DoD in TM5-809-1 "Load Assumptions for Buildings"

is ANSI Standard A58.1-1982, "Minimum Design Loads for Buildings and Other Structures." Sponsorship of that national standard has recently been transferred to the American Society of Civil Engineers. ASCE expects to publish a new version of A58 in 1988. For the past two years the ASCE snow loads subcommittee has been active in updating the snow load design criteria in that standard. Some revisions have been made to the ground snow load maps in Minnesota and the Dakotas Sliding snow provisions have been changed and drift load calculations have been expanded to include an appreciation for the length of the upwind roof.

ROOF DESIGN IN COLD REGIONS.

Tobiasson, W., Corps of Engineers Structural Fagineering Conference, St. Louis, Missouri, June 2⁷-July 1, 1988, Vol.2. Washington, D.C., Directorate of Engineering and Construction, 1989, p.1029-1037.

ROOFS, DESIGN, CONDENSATION, DRAIN-AGE, SNOW SLIDES.

AGE, SNOW SLIDES.

Roofs continue to be a problem in cold regions even though many excellent membrane and water-shedding systems are available. Compact (tightly built) systems suffer far fewer condensation problems than do framed roofing systems that tend to leak much more air. Air leakage, not vapor diffusion, is the cause of most condensation problems. Dead flat roofs of any type are a design mistake. In cold regions, membrane roofs should have a slope of 1/4 in /ft and should drain internally. It is usually best to slope all roofs by inclining the frame rather than using tapered insulation. Most water-shedding roofs drain to cold eaves and are thus subject to ice dam problems. Such problems can be minimized by designing a "cold" ventilated roof, insulating it well, by minimizing the overhang at the eaves, by increasing the roof slope and by providing an unobstructed slippery surface from which snow will slide However, when using slippery-surface from which snow will slide However, when using slippery-surface from which snow will slide However, when using slippery-surface systems, it is essential to provide a place for the snow to slide where it will not endanger people or damage property.

MP 2652 STRUCTURE AND TEMPERATURE DEPEND-ENCE OF THE FLEXURAL PROPERTIES OF LABORATORY FRESHWATER ICE SHEETS. Gow, A.J., et al, July 1989, 16(3), p.249-270, 13 refs. Ueda, H.T.

LAKE ICE, ICE COVER STRENGTH, ICE CRYSTAL STRUCTURE, FLEXURAL STRENGTH, STRAIN TESTS.

STRAIN TESTS.

Small-beam testing was conducted in a test tank on ice corresponding in structure to the two major ice types, S-1 and S-2, encountered in lake ice-sheets Tests of 730 beams in the temperature range -1 to -19 C showed that macrocrystalline (S-1) and columnar (S-2) ice differ appreciably in their flexural characteristics and that these differences are attributable to variations in the size and orientation of the crystals in the ice and the thermal condition of the beams Beams of S-1 ice yielded flexural strengths mid-way between those measured on S-2 ice.

The microwave radiative characteristics of the Weddell Sca ice were investigated from the R/V Polarstern during winter 1986 through, approximately, 3000 km of ice, from the marginal ice zone to the coastal region and back. Radiometer measurements at 6, 10, 18, 37, and 90 GHz in vertical and horizontal polarizations were complemented by visual and video observations and measurements, at 60 station, and norizontal polarizations were competentice by visual and video observations and measurements, at 60 station, of ice physical characteristics. Two distinct types of ice cover were observed in the marginal ice zone, small paneakes evenly distributed during the southbound leg. Other ice types observed were first-year ice covered by varying thicknesses and states of snow cover, and new and young ice found mainly in leads and polynyas. Analysis of the data shows a large variability in the multispectral microwave emissivities of these ice types, especially at 90 GHz. Overall, however, at 18 GHz and lower frequencies, the emissivities of thick and cold first-year ice are relatively stable with standard deviations of about 0.02. At the marginal ice zone, the emissivity of the ice cover is a lot less predictable and could cause large uncertainties in ice concentration estimates. The use of the 90-GHz channel in combination with a lower-frequency channel shows strong potential for more detailed characterization of the ice cover including the identification of varying snow cover and roughness. TEMPERATURE VARIATIONS.

This paper describes a simplified model for predicting the surface temperature of a snow cover By separate application of the model to natural snow and snow compacted by a moving vehicle, it is possible to determine the term. I contrast between the two surfaces. Inputs to the model utilize routine meteorological observations and certain initial characteristics of the snow cover and underlying ground. Established energy transfer equations are used to describe the last believe in the story cover and uncertainty actived by the heat balance in the snow cover and are solved by the method of finite differences, wherein the snow is divided into layers, and the temperature structure is evolved over time in finite time increments. While the methodology tune in finite time increments. While the methodology of more claborate energy and mass balance models is closely followed, snow cover in the current model is described in only three layers, providing a closed-form mathematical solution that requires little computer time

At SNOW-TWO fast responding instruments were used to measure the turbulent fluctuations in the wind speed, temperature, and humidity in the atmospheric surface layer over snow. Two crossed hot-film anemotiteters yielded the turbulent longitudinal (u) and vertical (x) components of the wind vector. A fine-wire platinum resistance thermometer and a Lyman-alpha hygrometer gave the turbulent temperature (t) and humidity (q) fluctuations, respectively Spectra of u and w have inertial subranges that are typical of velocity spectra measured in the atmospheric surface layer. The t and q spectra and the t-q cospectra all have distinct incitual-convective subranges. These are rarely found in simultaneous t and q spectra because the measurements are difficult. Consequently, this seems to be a high quality set of temperature and humidity spectra. Diverse u, w, t, and q spectra and the t-q cospectra collapse into universal forms when nond-circustonalized with appropriate dissipation forms when nond-circustonalized with appropriate dissipation or sets for velocity and the individual scalar and when the turbulence frequency is properly scaled. From the t and spectra and the t-q cospectra the first refractive index spectra for visible and millimeter wavelength light ever measured over snow are computed.

SOIL TRAFFICABILITY, SOIL WATER, METEOROLOGICAL DATA, WATER CONTENT, TESTS, MAPS, MODELS
The US Army Cold Regions Research and Engineering Laboratory (CRREL), with technical assistance from the Dartmouth College Physics Department, has developed a radio-frequency soil moisture sensor that measures the electrical resistance and capacities of a soil sample and converts the readings to volumetric water content. The soild-state sensor is mechanically rigid, small, and lightweight. It can obtain soil moisture and frost data in near real time and can be interfaced with communications systems for remote interrogation. The soil moisture sensor was laboratory tested and its accuracy was calculated at 37. The data also indicated that the vensor readings were independent of soil type and density. The next step for fielding the sensor was to test it under real winter battlefield conditions

Measurements were made of the angular distribution of power scattered from a diffuse reflector illuminated by a laser beam. Probability density functions of normalized signal strength for near normal scattering were also compiled Experiments were made on dry, wet and uce-covered planar targets. The results show that the diffuse component of scartered power from a wet or ice-covered target is reduced by an amount proportional to the inverse of the square of the index of refraction of the layer—a result consistent with simple theory. Backscattered radiation from a water or ice-covered target se enhanced over that from a dry target in the region about a cone centered on the line normal to the target. The aperture of the cone was greater for the ice-coated target. The difference may be due to small air bubbles in the ice. Because the surfaces of many military targets behave as diffuse reflectors, a simple calculation was made showing the effects of water and ice on laser rangefinder performance. A combination of theoretical and empirical results shows that the return from water and ice-coated targets will be stronger than that from dry targets in the near-zero-degree backscatter direction. As the angle of incidence increases to about 20 deg the coated targets will return almost a factor of two less power than the dry target.

GY), SYNOPTIC METEOROLOGY.

The atmospheric icing climatologies of two New England mountaintops with different elevations are compared. Mount Mansfield in northern Vermont and Mount Washington in New Hampshire. Atmospheric icing, as measured with Rosemount ice detectors, is twice as frequent on Mount Washington with about 12 to 20 times greater intensities and 25 to 50 times more accretion as on Mount Mansfield Most of Mount Mansfield icing events are of low intensity, with periods between icing events averaging 35 to 45 hours on both peaks. Return intervals of ice events by length, intensity, and accretion amount are tabulated. Approximately one-half of all severe icing on the two peaks occurs during and immediately after cold front passages. Icing is most intense when lows are about 450 km to the east and high pressure centers are more than about 450 km distant. Prolonged accretion periods occur when coastal and inland storms merge or follow closely.

TORS, COLD WEATHER TESTS, SAMPLING.
The air change rates of five buildings (four barracks and one vehicle maintenance garage) were measured, using the tracer gas dilution technique.

The median air change rate for all zones measured was close to 0.5 air change per hour (ACH). The range of air change rates was between 0.05 and 1.75 ACH. Most of this range was attributable to variation in the effective ess of the buildings ventulation systems.

Outdoor temperatures were between -15 and -20 deg C (5 and -4 deg F). The wind was calm for all but one barracks measurement. The maintenance facility, a large single-zone building, permitted good results from the tracer gas technique. The barracks multizone buildings, varied in the ease with which the tracer gas technique could be applied.

The barracks ventilation systems were in operation when air change measurements were made. These systems incorporated air-to-air heat exchangers with intakes and exhausts mounted in rooftop penthouses.

Hazardous waste treatment and disposal is one of the major environmenal concerns. In the United States alone, about 50 million tons of hazardous waste is produced each year Clay liners and clay caps are commonly recommended and used for containing and covering hazardous and toxic waste as well as solid municipal waste. The purpose of the liners is to impede the flow of contaminants to ground water and to sorb the chemicals, thus protecting the ground water from contamination. The purpose of the caps is to prevent water infiltration into the contaminated soil and the release of toxic gases. The objective of this study is to investigate the effect of freeze-thaw cycling on the

permeability and structure of compacted clay soils used as caps or barriers for containing hazardous waste materials. MP 2679

ALL TERRAIN VEHICLES, PERMAFROST, EN-VIRONMENTAL IMPACT, COUNTERMEAS-URES, SOIL STRUCTURE, DAMAGE, PROTEC-TION, UNITED STATES—ALASKA.

TION, UNITED STATES—ALASKA.

Use of off-road vehicles in permafrost-affected terrain of Alaska has increased sharply over the past two decades Until the early 1960s, most ORV use was by industry or government, which employed heavy vehicles such as industrial tractors and tracked carriers Smaller, commerc ORVs became available in the 1960s, with the variety and number in use rapidly increasing. Wheeled and tracked ORVs, many used exclusively for recreation or subsistence harvesting by individuals, are now ubiquitious in Alaska. This increased use has led to concern over the cumulative effects of such vehicles on vegetation, soils, and environmental variables including off-site values. Factors affecting impact and subsequent restoration include specific environmental setting, vegetation, presence and tiee content of permafrost, incretopography, vehicle design, weight, and ground pressure, traffic frequency, season of traffic, and individual operator practices Approaches for mitigating adverse effects of ORVs include regulation and zoning, terrain analysis and sensitivity mapping, route selection, surface protection, and operator training MP 2683 MP 2683

UNFROZEN WATER CONTENTS OF UNDISTURBED AND REMOLDED ALASKAN SILT. Tice, A.R., et al, Dec. 1989, 17(2), p 103-111, 13 refs.

Black, P.B., Berg, R.L.

FROZEN GROUND, UNFROZEN WATER CON-TENT, SOIL COMPOSITION, SOIL ANALYSIS, FROZEN GROUND THERMODYNAMICS, NU-CLEAR MAGNETIC RESONANCE, SATURA-TION, TEMPERATURE EFFECTS, SOIL WATER. Unfrozen water content as a function of temperature was measured in the laboratory using pulsed nuclear magnetic

resonance (PNMR) for 16 undisturbed frozen cores acquired from the Northwest Alaska Pipeline Company Chilled Gas Test Facility The cores were then remolded and brought to their original densities and water contents, and unfrozen water content as a function of temperature was again measured over three warming and cooling cycles It was found that differences in unfrozen water contents between the undisturbed warming and cooling curves depended upon relative degree of saturation and its effect on soil structure Only slight changes occurred during the three warming curves of the remolded soil, indicating minor freezing and thawing consequences on the soil structure

GROWTH, SALT ICE, REFLECTION.

Sonar echo amplitude data have been collected at kilohertz carrier frequencies from the underside of different sea ice types. Histograms of normal incidence echo amplitudes were formed from over 90 samples of each tee type. Experiments were conducted on saline ice grown in an outdoor pond under relatively controlled conditions at CRREL and on the sea ice cover in the Fram Strait. Analysis shows marked variations (about a factor of 5) in the magnitude of the coherent reflection coefficients as congelation ice at the bottom of an ice sheet evolves from a growing dendritic interface to an ablating, thermally altered interface. Larger differences (about a factor of 10) are observed between growing congelation ice and slush ice, used to simulate frazil Transmission measurements through thin ice indicate that important attenuation processes are associated with bassil dendritic structure resulting in a high attenuation regime (5 dB/cm at 200 kHz) in roughly the bottom 10 cm of growing sea ice and low attenuation regime (0 1 dB/cm) growing sea ice and low attenuation regime (0 l dB/cm) consisting of the overlying ice. These results indicate that important variations in acoustic regime exist in areas where different ice types are intermingled

ICE MECHANICS, DRIFT, ICE NAVIGATION, MILITARY OPERATION, ICE PHYSICS, ICE CRYSTAL STRUCTURE, GRAIN SIZE, SEA ICE. ICE FORECASTING, MATHEMATICAL MOD-ELS. TESTS.

The approach to developing mechanistically-based predictive models discussed in this paper is by no means trivial deally, a stepwise approach should be taken. This would first involve the determination of the micromechanical processes involved in the deformation of the ice. We would begin by studying these processes in a relatively simple material, freshwater, equiaxed ice, and progress to the most complicated ice type, aligned, columnar sea ice. Once the phenomena

of deformation were well understood over the range of loading and environmental conditions, the attention would focus towards the development of a mathematical, mechanistically-based model of the ice behavior. The model would require input about the loading scenario (e.g. surfacing submanne sail, ship travelling through the ice sheet, convergence of ice sheets), the appropriate environmental conditions, and the corresponding physical properties of the ice. The predictive model would first be verified using scale-model test results and, once the accuracy of the model was proven, application would be extended to field conditions. The capabilities of the model to predict loads in the field would be evaluated by compansion of the predicted to actual stress measurements determined during field experiments. of deformation were well understood over the range of loading

DEFORMATION, 1ESIS, BUOTANCT.
Floating model ice sheets were lifted vertically and penetrated with cylindrical indentors of different shapes (flat, truncated-conical and conical) and diameters (76 mm, 152 mm and 305 mm) and in different ambient temperatures (0, 10, 20 F). The experimental results show that there is no effect of indentor shape or size on the ice penetration forces. From dimensional analysis, a relationship is obtained for maximum ice penetration force in terms of the specific weight of water, the ice thickness and the upward flexural strength.

FECTS, HUMIDITY.

Wintertime leads and polynyas are terrific sources of heat and moisture. Described here are some of the environmental effects of these large heat and moisture fluxes. For example, the arr near the water surface is supersaturated, the resulting fog can limit visibility, rime ice forms prolifically on any downwind structure, and for large leads and polynyas, massive plumes of condensate particles can alter the radiation budget of the downwind surface. Convectively driven turbulence fostered by the large fluxes enhances the vertical mixing For large open water areas, the convection may be intense enough to jostle low-flying aircraft.

GROWTH, SOIL WATER MIGRATION, ANALYSIS (MATHEMATICS), GROUND ICE.
The steady growth of a segregated ice layer in freezing
soils is studied mathematically under three distinct and representative hypotheses on the properties of the frozen fringe,
chosen among many such hypotheses reported in the literature.
It was found that the condition of steady growth is determined
by the temperature radient in the unforce next of the It was found that the condition of steady growth is determined by the temperature gradient in the unforcen part of the soil at the 0 (C) isotherm and the temperature gradient in the ice layer at the interface between the ice layer and the frozen fringe in all three hypothetical models studied. The transport equation of water in the frozen fringe was found to be the major factor determining the condition of steady growth. This is the first of a two-part presentation on the subject, the experimental aspects of the study will be presented in a second paper.

FACE PROPERTIES.

The overland flow system involves applying wastewater to the upper elevation of a carefully prepared grassed slope. The wastewater flows down the surface of the slope through the grass, it is collected at the bottom of the slope and may be discharged to a stream or, perhaps, to a rapid infiltration site. While flowing down the slope, some loss in volume occurs due to evapotranspiration and infiltration, although these losses are usually small due to the short length of slope employed and the impervious nature of soils which favor this method of treatment. The hydraulies of shallow flow down wide grassed channels has received some attention when the flow regime is turbulent. The L.S. Environmental Protection Agency sponsored Storm Management Model uses the Manning equation to describe shallow overland flow, but this approach is suspect when the flow occurs in the laminar regime. Experimental measurements by the Corps of Engineers show that overland flow occurs in the laminar regime with the Reynolds number less than 20 based on grass dameter, taken as 0.001 m. and less than 20 based on grass dameter, taken as 0.001 m. and less than 20 based on grass dameter, taken as 0.001 m flows down the slope of an overland flow system is developed.

PERFORMANCE OF AN OMNI-DIRECTIONAL WHEEL ON SNOW AND ICE.

DRAINAGE, CAPILLARITY, FREEZING.
Sludges are easily separated into solid and liquid fractions by freezing and thawing. Water and wastewater treatment plants in cold climate areas can take advantage of this process by freezing and thawing sludge during the winter and summer seasons in a new unit operation called a sludge freezing bed. The purpose of this study was to measure the dewaterability of freeze-thaw conditioned sludges and measure how well they drain at various depths. Typical water treatment, anaerobically digested and aerobically digested sludges were tested. The mair conclusion of this study was that up to 2.0 m of these sludges could be applied to a freezing bed.

MENT.

Nondestructive measurement and analysis of moisture absorption and migration in polyurethane insulation material subjected to a prolonged water exposure were performed using a dual-energy gamma-ray device. The parameters influencing moisture absorption by a given type of insulation were found to include (a) the insulation density, (b) the insulation were found to include (a) the insulation density, (b) the insulation thickness, (c) the presence of a vapor barrier or jacket, (d) the type of insulation jacket and (e) the time of exposure to moisture. With time, the variation of any of these factors would cause a change in moisture gradient across the insulation thickness. For this investigation, the effects of the insulation thickness, exposure time to moisture and the presence of a vapor jacket were evaluated and quantified for polyurethane insulation. Also, a preliminary test was performed with a frozen polystyrene breadboard to evaluate the measurement accuracy by the gamma-ray method in determining nondestructively the insulation moisture content and profile. and profile

STEELS.

The purpose of these studies was to compare PVC, PTFE, SS 304 and SS 316 well casings for monitoring metals and organic compounds in well water. Review of the literature revealed that these commonly used well casing materials had not been studied concurrently. These studies used well casings manufactured specifically for ground water monitoring and water obtained from a 76-m-deep domestic well in Weathersfield, VT. No attempt was made to maintain issolved oxygen, carbon dioxide, temperature, pH or redox potential levels representative of ground water, and this undoubtedly had an effect on analyte speciation. Because of these factors, the static laboratory conditions, and exposure of freshly cut surfaces on the well casings, the results will not quantitatively predict what might occur under field conditions. Nevertheless, since spiked analytes varied relative to the control by more than 10% after only 8 hours of exposure, and leaching experiments showed analyte concentiations greater than 5% of the present EPA drinking water quality standards, it is the authors' opinion that there is a basis for concern, especially for shallow wells with a slow recharge.

ISTICS, SURFACE PROPERTIES

The newly marketed Caterpillar agriculture tractor, called the Challenger 65, was evaluated in snow covered terrain to determine its potential as a prime mover for operations in Antarctica. Three vehicle configurations were tested with the standard belt, with the standard belt carrying studs, and with a specially constructed wide track to improve flotation. Rolling resistance and drawbar pull were measured on ice, hard packed snow and in deep, relatively soft snow General handling and ride were evaluated qualitatively. It was found that the tractor is rugged, well constructed, is easy to operate and has the normal ride quality associated with vehicles having short wheelbases. The results of

the evaluation are very encouraging and led to the conclusionate the machine should receive serious consideration for application in the Antarctic for transport problems that may soon appear that involve the use of sled trains.

BAY.
Field observations made during the Mar. 1988 BEPERS (Bothnian Experiment in Preparation for ERS-1) remote sensing experiment allow limited characterizations of the temperature, salinity, structure and physical property profiles of the different types of bracksh ice that forms in the Bay of Bothnia. During the sampling period, undeformed fastice thicknesses varied from 40 to 60 cm in the bay to the east of Umea, Sweden, with somewhat thicker ice occurring in the northermoust, nearly fresh, portions of the bay Ice salinities were generally less than 1 per mill and the ice temperatures were usually higher than -3.5 C. Although most of the ce examined was simple columnar congelation ice, a variety of castis fabrics were observed, including random, vertical and horizontal (random and aligned) onentations. There was no obvious pattern to the geographic arrangement of these fabrics. Brine volume profiles are used to estimate representative corpoperty profiles. Comparisons are made between the properties of ice from the Bay of Bothnia and those of more typical sea ce from the Arctic Ocean at similar ice thicknesses. A variety of structural factors contributing to specific areas of higher radar return in the bay are also discussed.

SNOW COVER EFFECTS ON ANTARCTIC SEA ICE THICKNESS.

SURFACE PROPERTIES, MODELS, ANTARC-TICA—WEDDELL SEA.

In model simulations of seasonal pack ice growth in both polar regions (e.g., Maykut and Untersteiner 1971, Semtner 1976, Hibbler 1979), the snow cover is treated essentially as an insulating layer that inhibits ice growth because of its lower conductivity than pack ice. In the Winter Weddell Sea Project-86, on the cruise of the West German vessel Polarstem, several factors were found that negate this behavior predicted by the mooels. Relatively thin sea ice (40-60 cm) forms initially in Antiarctica during the ice edge advance. Surface roughness features act as snow fences and, under the action of relatively high winds (40 knots in frequent storms), the snow cover is shifted around over periods of hours to a few days. Wind-blown snowdrifts build to 1 m or greater thicknesses in a few injurs. Snow of this depth can easily depress the existing ice cover surface below sea level, and flooding of the snow cover followed by sub-freezing temperatures leads to a superimposed snowice layer on the top surface. The remaining snow cover is redistributed in the next storm within a few days to continue the process. Two sets of measurements showed the general nature of this process. The first, a series of 4000 ice thickness measurements, showed about 17% of the holes drilled had the ice surface at or below sea level at the time of the measurement, sometimes accompanied by slush pools on the surface. Sea ice cores analyzed for oxygen isotopes independently confirmed that the top 10-20 cm of the intact cores was derived from seawater-flooded snow in secveral cases. It was estimated that the snow cover increases mean sca ice thickness in Antarctica by 20-30% (10-20 cm) over model predictions by this flooding-infiltration-refreezing ice growth mechanism (Auth.)

FACTORS, OCEANOGRAPHY, GRAIN SIZE, PHOTOGRAPHY, COMPUTER APPLICATIONS, ANTARCTICA—WEDDELL SEA.

The physical and biological properties of sea ice are governed to a large extent by us texture. The texture of a sea-ice cover, on the other hand, is controlled by the meteorological and oceanographic conditions under which growth took place. Textural analysis can thus provide insight into the formation and development of sea ice, and at the same time it represents the central link between the evolution and the properties of an ice cover. Studies of sea-ice thin sections taken from the Weddell Sea have generally relied on subjective, qualitative evaluations of texture. Aside from c-axis distributions determined with a Rigaby stage, textural characteristics such as grain size or shape are usually not evaluated because the procedure is time-consuming (as is determination of c-axis distribution) or even impossible. The complex texture of sea ice—with intertwining grains of diverse shapes, numerous inclusions of brine and gases between and within grains, and sub-grain boundaries—often delies common notions of "grains," "grain size," etc. The introduction of automatic exture analysis might be helpful in overcoming the difficulties outlined above the method allows quantification of textures, permitting direct comparison between large numbers of samples, which is difficult or impossible to achieve through qualitative examination. Automatic texture analysis also overcomes personal bias inherent in conventional methods by collecting and considering all the information (i.e., all gray values) available for one thin section. SNOW DEPTH.

The reflection, absorption, and transmission of light at visible and near-infrared wavelengths is important for a number of geophysical problems. Light reflection is an important to ice thermodynamics, and transmission strongly influences biological activity in and under the ice. The focus on this paper is on the spectral (wavelength region 400-1000 nm) reflection and transmission of light by spatially inhomo-

geneous sea ice covers investigated using a two-stream, multilayer radiative transfer model

The model is computationally simple and utilizes available experimental data on the optical properties of sea ice. The ice cover is characterized as a layered medium composed of selections from nine distinct snow and ice types. Two cases are presented illustrating values of spectral albedo, transmittate, and transmitted PAR (photosynthetically active radiation) for a uniform ice cover as it melts and for a spatially inhomogeneous ice cover. The importance of ice thickness and surface conditions on the spectral reflected and transmitted radiation fields is demonstrated.

Sonar echo amplitude data have been collected at carrier rrequencies of 188 and 120 kHz from the underside of different sea ice types. Histograms of normal incidence echo amplitudes were formed from over 90 samples of each ice type Experiments were conducted on saline ice grown in an outdoor pond under relatively controlled conditions at CRREL and on the sea ice cover in the Fram Strait. Analysis shows marked variations (about a factor of 5) in the magnitude of the coherent reflection coefficients as congelation ice at the bottom of an ice sheet evolves from a growing dendritic interface to an ablating, thermally altered interface Larger differences (about a factor of 10) are observed between growing congelation ice and slush ice, used to simulate frazil These results indicate that important variations in acoustic regime exist in areas where different ice types are intermingled

COMPARISON OF THE COMPRESSIVE STRENGTH OF ANTARCTIC FRAZIL ICE AND LABORATORY-GROWN COLUMNAR ICE. Richter-Menge, J.A., et al, Feb. 1990, M 90-01, Sea

ICE MICROSTRUCTURE, STRESSES, ANTARC-TICA—WEDDELL SEA.

Unconfined, uniaxial compression tests were performed on frazil sea ice samples collected in the Weddell Sea. The tests were done at a constant strain rate of 1/100 1/s and at temperatures of -3, -5 and -10 C. Data from the frazil ice tests were compared to results from tests done under the same conditions on transversely isotropic, columnar saline ice. The approximate grain sizes of the frazil and columnar ice were 1 and 10 mm, respectively. The results of this work indicate that the frazil ice generally has a higher strength than columnar ice loaded in the plane of the sheet. Tests done by other researchers on freshwater, equiaxed polycrystalline ice have also shown the compressive strength to vary inversely with grain size. Application of this relationship to the sea ice tested indicates that the results from these freshwater ice tests at a strain rate of 1/100 1/s cannot be directly extended to explain the variation in compressive strength between the frazil and columnar sea ice. It is speculated that this may be due to 1) the influence that the increased ductility of sea ice has on the relationship between strength and grain size at 1/100 1/s, 2) that another microstructural parameter (e.g., the thickness of the ice between brine inclusions) may be the con rolling factor in determining sea ice strength, or 3) that the dominant mechanisms driving deformation vary with each ice type (Auth)

A report is given on a large-scale survey of the Weddell Sea pack ice and water column carried out during the Winter

Weddell Sca Project 1986 (WW2P '86) from midwinter to austral spring It was concluded that the incorporation of Neogloboquadrina pachyderma into sea ice is related to ice formation processes, and that their incorporation into the ice is not necessarily accidental but may indicate an overwintering strategy. These observations can have implications for the use of N. pachyderma as a marker for water masses, since forammilers growing in the ice may have a different isotopic configuration from those living in seawater only. DETECTION.

Remote sensing using an airborne infrared lidar has shown an unexpected capability to detect open leads (linear openings) in arctic sea ice and their associated meteorology in winter It is shown that vertical profiles of backscattered radiation demonstrate strong returns from hydrometeor plumes originating from leads having a surface water temperature near -1.8 C. Recently refrozen leads are also distinguishable by the lidar backscatter from adjacent shicker, older sea ice. Wide leads release enough energy to create buoyant plumes which tenetrate the arctic boundary layer inversion, transporting heat and moisture into the troposphere. These results show that the role of the Arctic as a global heat sink may need to be re-evaluated, and that lead plumes have a significant effect on the radiation budget.

POLYNYAS, WIND FACTORS, SEA ICE, ICE MECHANICS, LATENT HEAT, CLIMATIC FAC-TORS, DISTRIBUTION, DRIFT, BERING SEA.

TORS, DISTRIBUTION, DRIFT, BERING SEA. The relationship of winds derived from mesoscale meteorological networks to polynya sizes and onentations was investigated Defense Meteorological Satellite Program imagery was merged with atmospheric pressure network data from the Bering Sea for Mar. 1988 During the month, wind systems drove sea ice southward, creating and maintaining polynyas south of St. Lawrence, St Matthew, and Nunivak Islands. Existing land stations, the deployment of a moored pressure buoy south of the ice edge, and a rew automated weather station on St. Matthew Island have allowed the "creation" of meso-networks that surround these lee-shore polynyas This analysis (rather than synoptic) has shown that polynya lengths and orientations can be simply related to the mesonet computed geostrophic winds. The typical time lag between the onset of a geostrophic wind and the appearance of "windsock" type tracking of the polynyas is 24 hours MP 2735

SEA ICE, TOPOGRAPHY, ICE SURFACE, REMOTE SENSING, LIDAR, SURFACE ROUGH-NESS, PRESSURE RIDGES, PHOTOGRAPHY.

NESS, PRESSURE RIDGES, PHOTOGRAPHY. During a multinational remote sensing experiment in May 1987, the NASA Airborne Oceanographic Lidar (AOL) was used to collect profiles of the sea ace surface topography in the eastern Arctic. A Global Positioning System (GPS) receiver was used to provide aircraft positioning to an accuracy of about 50 m. The AOL is a pulsed laser that provides a profile free of phase shift discontinuities common to continuous wave lasers. Similar to other laser data, however, the aircraft altitude variation requires removal from the profile prior to calculation of the ice surface roughness statistics As with previous data, there remains an uncertainty as to the freeboard level of the ice after the aircraft motion has been removed, thus small-scale roughness statistics are considered unreliable. However, statistics of pressure ridges can be generated with confidence. The statistical results of ndges from this data set consisting mainly of ridge height and frequency distributions, compare well with previous results obtained from this area of the Arctic. Consistent with

previous findings, the AOL data indicate that while the regional mean ridge heights from the area north of Greenland are similar to those reported for other parts o' are Arctic, the average kilometer contains substantially more ridges than have been observed in other Arctic locations.

ELECTRICAL PROPERTIES, AIR TEMPERA-TURE.

In this paper the possibility of extracting geophysical information about the great ice sheets from passive microwave data is explored. This work was stimulated by calculations done by Zwally (1977) who showed that typical snow grain sizes at the surface of the ice sheet measurably influence the microwave emissivity of the near surface. This result led to speculation that ice-sheet-wide accumulation rates could be estimated by using empirical relations between grain size and accumulation rate, but little quantitative progress has been made towards that goal using single channel radiometer data alone. Data from the Scanning Multichannel Microwave Radiometer are now in a convenient format for analysis, prompting us to perform a qualitative analysis of the 18- and 37-GHz vertically and horizon-tally polarized data, in the context of Zwally's earlier work. An additional premise of the investigation is that this analysis can be simplified by hypothesizing that large-scale glaciologic regimes trive characteristic surfaces controlled by local environmental conditions. In turn, characteristic surface properties contribute to unique microwave signatures. To test whether a segmentation of the SMMR data set into particular glacial regimes could be used to identify differences between the physical properties of each regime, mean monthly brightness temperatures were examined at 18- and 37-GHz for both horizontal and vertical polarizations over frive areas. Measurable differences were found between brightness temperature trends for the different areas that were attributed, in part, to fluctuations in the large-scale surface temperature field of the ice sheet. ICE MODELS, SEA ICE, CAVITATION, OCEANS, CLIMATIC CHANGES, ICE COVER EFFECT. RHEOLOGY, SEA WATER, ICE COVER THICKNESS, FLUID DYNAMICS, ICE MECHANICS.

The motivation for the present work is the development The motivation for the present work is the development of a sea ice theology parameterization that retains most of the essential physics of large-scale drift, yet is conceptually simple and computationally fast enough to be useful for long-term climate studies. The approach is to reformulate the velocity correction method of Nikiforov et al. (1967) and Parkinson and Washington (1979) and obtain the so-called cavitating fluid theology. The ristinale is that packing can be viewed as a two-phase medium (in two dimensions), one phase being ice and the other open water. The open

water phase is considered to have no strength and so convergence will reduce the area of open water. The ice phase has some strength and so convergence is restricted if no open water is present.

Divergence, on the other hand, is unhindered and causes open water to be created. In the model discussed here, the ice pack is assumed to have no shear strength which, aithough counternituitive, has certain advantages first, the model is much simpler; and second no shear strength which, aithough counternituitive, has certain advantages first, the model is much simpler, and second, a more robust (and realistic) circulation of the ice is maintained for wind fields averaged over periods of days or weeks By incorporating the cavitating fluid rheology into a complete dynamic-thermodynamic sea ice model and performing several three year simulations of the arctic sea ice cover, the effect of various parameters and time step lengths can be evaluated. Comparison with the more complete viscous-plastic model of Hibler (1979), which includes shear strength, yields insight into the effects of this simplified parameterization.

ARTIFICIAL ICE, SEA ICE, MEASUREMENT, RADAR ECHOES, BACKSCATTERING, ICE SURFACE, ANTENNAS, ICE GROWTH, SNOW COVER EFFECT, SURFACE EFFECT, WAVE PROPAGATION.

During the 1984 and 1985 winter seasons, radar backscatter During the 1984 and 1985 winter seasons, radar backscatter measurements were performed on artificial sea ice at the US. Army Cold Regions Research and Engineering Laboratory (CRREL) at Harder, NH. Radar data were collected at selected frequencies in the 4-17 GHz region for incidence angles from 0 to 60 deg with like and cross polarizations. These measurements were performed on smooth, rough, bare and snow-covered saline ice and open water. Backscattering from ice increased with its thickness until the ice was about 1 cm thick and then decreased gradually with further growth Rough ice and snow-covered ice gave similar returns at 13 6 GHz, but the scattering coefficients of snow-covered ice were lower than that of rough ice at 9 6 GHz. Depolatized scattering from smooth, thin ice and water were much lower than from rough ice and snow-covered ice.

WATER CHEMISTRY, LABORATORY TECH-NIQUES, CHEMICAL ANALYSIS, CHEMICAL COMPOSITION, SOLUBILITY, CHEMISTRY

It appears there has been very little exploitation of salting out with water-miscible solvents for extraction of organic solutes from water Although this technique is known to many chemists, we found no specific literature references to many chemists, we found no specific literature references to salting-out of organic compounds as a prelude to their determination in water, save one recent abstract. This technique has, however, been used for a number of years for extraction of metal-chelates into organic solvents prior to atomic absorption, high-performance liquid chromatography, polarographic, or colorimetric analysis. So, although we freely acknowle'; e that the technique itself is not new, we do feel that its potential "polications in organic trace analysis of water have not been properly appreciated or utilized. We describe here just one of many possible examples, which has found considerable utility in our laboratory.

The CRREL Instrumented Vehicle (CIV), and shear annulus direct shear and triaxial compression test devices w to measure the strength of thawed and thawing soil. to measure the strength of thawed and thawing soil. These strength values can be used in simple traction models to predict the tractive performance of vehicles. Strength was evaluated in terms of the parameters c and phi based on the Mohr Coulomb failure critetion. It is proposed here that an instrumented vehicle is best suited for terrain characterithat an instrumented whicle is best suited for terrain characterization for mobility studies because the conditions created by a tire slipping on a soil surface are exactly duplicated. The c and phi values from the shear annulus were found to overpredict traction because of the low normal stress applied by the annulus and the curved nature of the failure envelope. Of all the tests, the direct whear test yields the highest phi value. This was most likely because the test was run at a slow deformation rate, under drained conditions. The triavall test results were the most similar to those from the vehicle. All test methods show phi increasing with soil moisture up to the plastic limit of the soil and then decreasing. Phi as neasured with the vehicle was also found to be strongly influenced by the thaw depth.

OPTICS.
In this paper a quantitative analysis of uniaxial crystal orientation data is developed. Though the method is general, we focus on the application of the analysis to ice fabrics. The crystal orientation data are represented as points on the surface of a unit sphere. An orthogonal least-squares error measure is used to develop equations that define the closest plane and line through the data while retaining all coordinate directions as independent variables. For comparison, a parallel develope, ent is presented of the standard dependent variable least-squares determination of the best plane. The orthogonal error measure quantifies the good-ness-of-fit to the data of all approximate representations. Finally, a technique is developed to generalize from the standard Schmidt net presentation of data in the xy-plane to a presentation in any of the three planes defined by the Cattesian coordinate system. SNOW COMPOSITION, CHEMICAL PROPERTIES, ION DIFFUSION, SNOW CRYSTALS, MELTWATER, ADSORPTION, ICE WATER INTERFACE, CHEMICAL ANALYSIS

In this study we investigate whether or not grains of metamorphosed snow (ice crystais) can act as a chromatographic column selectively adorbing and retaining inorganic ions. The chromatographic process has been proposed as a potential mechanism to explain the preferential elution of inorganic ions observed in water from melting snowpacks. Experiments were conducted using a 18 cm diameter by 30 cm long. Pyrex glass column filled with frozen droplets and natural snow grains. Denonized water and solutions containing known dilute concentrations of sulfate, nitrate and chloride were then slowly allowed to flow down through the column and the cluant was collected in 1 ml, abspaces. An experiment specifically designed to detect chromatographic effects showed all three species appeared at the bottom of the column simultaneously, indicating that we surfaces exhibit no preferential affinity for these anions. In this study we investigate whether or not grains of metamorMP 2756

CLASSIFICATIONS.

Operational winter meteorology deals with problems that depend on the area, volume or number of snowflakes in the air. The irregular shape of typical aggregated snowflakes requires special techniques for calculation of area, volume or number from mass precipitation data. Atmospheric aerosols, paint pigments, and other fine particles have very irregular shapes but are several orders of magnitude smaller than snowflakes. The statistical techniques developed these fine particles can be applied to snowflakes to estimate the visibility, rate of surface coverage and other area- or volume-dependent operational parameters. It appears that these techniques can be broadly applied to generalization of the physical properties of airborne snow

ICE OPENINGS, CLOUD DROPLETS, AIR WATER INTERACTIONS, LIDAR, AEROSOLS, POLYNYAS, ANALYSIS (MATHEMATICS), HU-MIDITY.

With an airborne lidar, massive plumes of condensate particles rising from wintertime leads in the Arctic Ocean have been observed. Some of these plumes reached an altitude of 4 km; some extended over 200 km down-wind from their surface source. Here we invert the lidar equation and 4 km; some extended over 200 km upwirms to surface source. Here we invert the lidar equation and use lidar backscatter data to infer particle concentrations within two such plumes. Assuming that the plumes consist of supercooled water droplets of radius 5 micron, typical concentrations of 300,000-600,000 droplets/cu m just above the leads is estimated Concentrations within the plumes can still be as high as 10,000 droplets/cu m at an altitude of 3 km and 200 km down-wind from some leads. Had it been assumed that the plume particles are ice spheres of radius 40 microns, concentrations would be just 100 times leas than these.

SEA ICE DISTRIBUTION, ICE MELTING, SOLAR RADIATION, MATHEMATICAL MODELS, ICE WATER INTERFACE, ICE COVER THICKNESS, ICE AIR INTERFACE, ICE MOD-ELS. ICE EDGE.

Sea ice covering the polar oceans is only a thin veneer whose areal extent can undergo large and rapid variations in response to relatively small changes in thermal forcing Positive feedback between variations in ice extent and global abodo has the potential to amplify small changes in climate Particularly difficult to model is the summer decay and retreat of the ice pack which is strongly influenced by shortwave radiation entering the upper ocean through leads. Most models assume that all of this energy is expended in lateral melting affine edges. In reality, only a portion of shortwave radiation contributes directly to lateral melting, with the temainder going to bottom ablation and warming of the water. This partitioning of shortwave radiation affects not only the magnitude, but also the character of the jacdicted rice decay, reducing the change in see concentration and enhancing the thinning of the ice and the storage of heat in the water. In this paper an analytical model is presented which includes many of these processes and is stable regardless of time step, making it suitable for use in climate simulations Sea ice covering the polar oceans is only a thin vencer

ICE COVER THICKNESS.

The focus of this paper is on the reflection and transmission of light by spatially inhomogeneous and temporally varying sea are covers. This is investigated using a two-stream, multilayer radiative transfer model in the wavelength region from 400 to 1000 nm. The model is computationally simple and utilizes the available experimental data on the optical properties of sea are. The ice cover is characterized as a layered medium composed of selections from nine distinct anow and ice types. Three case studies are presented illustrating values of spectral albedo, transmittance, and transmitted photosynthetically active radiation (PAR) for (1) a spatially inhomogeneous are cover, (2) a uniform ice cover as it undergoes a melt cycle, and (3) a temporally changing spatially variable ice cover. Results indicate that small-scale horizontal variations in snow depth and ice thickness. spanishly variation the cover Results indicate that small-scale horizontal variations in snow depth and ice thickness can cause I th transmission to change over 3 orders of magnitude. ICEBREAKERS. METAL ICE FRICTION, IC NAVIGATION, ANALYSIS (MATHEMATICS).

This paper presents the results of resistance and propulsion tests in level ice of a 120 scale model of the Canadian This paper presents the results of resistance and propulsion tests in level ice of a 120 scale model of the Canadian Coast Guard R-class recbreaker at two rec-hull finetion coefficients, performed at several ice testing facilities in various countries under the aegus of the Committee on Performance of Ships in Ice-covered Waters of the International Towing Tank Conference (ITTC). There is good agreement overall among the test results obtained at the various facilities. The differences that do remain should be attributed to differences in experimental techniques and types of model ice used at the participating laborateries. An increase in hull roughness led to an increase in ince resistance as expected, but had no effect on the propeller characteristics. While the thrust coefficient in ice was nearly the same as in clear water, the torque coefficient and thrust deduction factor were much greater in level ice than in clear water and nearly constant. Full-scale ship performance predicted from the resistance test results of the rougher model and the propulsion characteristics in clear water was in good agreement overall with available field trial data. Predicted performance using the ice resistance of the rougher model and the model propeller characteristics in ice was usually below that observed at full scale. This would indicate that ice-propeller interaction is egessive during model propulsion tests, or that the effect of ice entrainment on propeller performance is greater at model scale than at full scale. Ice-propeller interaction remains a domain where further research is needed

SEA ICE, SALT ICE, ICE SALINITY, ICE SUR-VEYS, REMOTE SENSING, ICE TEMPERA-TURE, ICE STRUCTURE, BOTHNIA, BAY.

TURE, ICE STRUCTURE, BOTHNIA, BAY.
Field observations made during the May 1988 BEPERS (Bothmian Experiment in Preparation for the ERS-1 satellite) remote sensing experiment allow limited characterizations of the temperature, salinity, structure and physical property profiles of the bracksh ice that forms in the Bay of Bothnia. During the sampling period, undeformed fast ice thicknesses varied from 40 to 60 cm in the Bay to the east of Umea, Sweden, with somewhat thicker ice occurring in the northernmost, nearly fresh, portions of the Bay. Ice salinities were generally less than 1 per mill and the ice temperatures were usually warmer than -3 5 C. Although most of the ice examined was simple congelation ice, a variety of c-axis fabrics were observed including random, vertical and horizontal (random and aligned) orientations. There was no obvious pattern to the geographic arrangement of these fabrics. Brine volume profiles are used to estimate representative ice property profiles. Comparisons are made between the properties of ice from the Bay of Bothnia and those of more typical sea ice from the Bay of Bothnia and those of more typical sea ice from the Arctic Ocean at similar ice thicknesses. A variety of structural factors contributing to specific areas of high radar return in the bay are also discussed. also discussed
